RELEVANT LOGICS, MODAL LOGICS
AND THEORY CHANGE

André Fuhrmann

A thesis submitted for
the degree of Doctor of Philosophy
of the Australian National University

Department of Philosophy and
Automated Reasoning Project
Research School of Social Sciences
September 1988
Except where otherwise acknowledged, this thesis is my own work.

[Signature]
Abstract

This thesis is a contribution to applied relevant logics. In Part One relevant logics are presented proof-theoretically and semantically. These logics are then extended to modal logics. Completeness proofs for all of the logics presented in Part One are provided. In Part Two, the logics of Part One are applied to certain problems in philosophical logic and Artificial Intelligence. Deontic and epistemic logics based on relevant logics are presented in chapter three and chapter four contains an extensive investigation of the logic of theory change (or database updating).
Acknowledgements

For all he taught me and for his perfect balance between penetrating criticism and unfailing encouragement, I wish to record my deep gratitude to my supervisor Dr Richard Sylvan. I also thank Prof Frank Jackson of the Department of Philosophy and Dr Michael McRobbie of the Automated Reasoning Project for providing a superb environment for carrying out the research recorded in this thesis. My thoughts on the topics of this thesis have been shaped in many discussions with past and present members of and visitors to the Department of Philosophy and the Automated Reasoning Project. Among those who have helped me in this way, I wish to thank in particular Peter Lavers, Prof Isaac Levi, Dr Errol Martin, Michaelis Michael, Dr Stephen Read, Dr John Slaney, and Prof Neil Tennant. Some of those mentioned have also been so kind as to comment in writing on various parts of this thesis.

I owe a great deal to the support of my friends during writing this thesis: Steve Buckle, Tim Burgess, Gerald Haberkorn, Peter Lavers, Philippa Mein Smith, Michaelis Michael, Jacques Riche, Kim Sterelny, and Igor Urbas. I shall forever be indebted to Prof Jack Smart and his wife Liz for making me feel at home in Canberra.

My wife Susanne ... SINE QUA NON. I would have dedicated this thesis to her, had my parents not a prior claim to this small token of gratitude. So I dedicate this thesis to my parents, Wolfgang and Irmgard Fuhrmann.

Last but not least: thanks to John Barlow for keeping up the Sun.
Contents

Introduction

Part One: Relevant Logics and Modal Logics

I. Relevant logics determined by R*-models

1. Language 5
2. R*-frames and -models 7
3. The system BM and the basic completeness result 10
4. Some further relevant logics 23

II. Modal logics

5. The language L
6. Relational semantics: R*S-frames and -models 35
7. C-modal logics and the basic completeness result 37
8. C-modal logics in context and semantics for some extensions of L.C 42
   8.1 A classification of modal logics 42
   8.2 Extensions of C-modal logics and their semantics 47
   8.3 Reduced frames for R.KT4 ? 52
9. Neighbourhood semantics: R*N-frames and -models 55
10. The basic completeness result for congruential modal logics 58
11. Extensions of L.E 62

Part Two: Applications

III. Modal logics for reasoning about theories

12. Formal properties of theories 66
13. Modal logics for reasoning about theories 70
   13.1 An extension of L by Basic Logical English 70
   13.2 Some benchmark differences between relevant and classical bases for modal logics 74
14. Interpreted modal logics I. Epistemic modalities 75
14.1. Acceptance sets. L.R as a basic logic of acceptance 75
14.2. Considerations about the choice of a base logic 79
14.3. Does fragmentation save classical acceptance logic? 81
14.4. Extensions of the basic acceptance logic L.R 87

15. Interpreted modal logics II. Deontic modalities 91
15.1. The descriptive interpretation of deontic logic 91
15.2. The choice of a base logic 97
15.3. Extensions of L.R and further deontic operators 99

V. Theory change

16. Three kinds of change: expansion, contraction, and revision 105
16.1 An overview 105
16.2 The Gärdenfors postulates for contraction 107
16.3 Explicit definitions of the contraction operation and the intuitive process of contraction 110

17. Contraction
17.1 Contraction on theories generated from irredundant bases 122
17.2 Contraction on theories generated from redundant bases 128

18. Multiple contraction
18.1 The definition of meet contraction 133
18.2 The definition of choice contraction 136
18.3 The generalised Gärdenfors postulates for multiple contractions 142
18.4 Choice contraction and conjunction contraction, meet contraction and disjunction contraction, and iterated contraction 149
18.5 Is (finite) choice-contraction conjunction-contraction? 155

19. Contractions and revisions 157
19.1 Meet revision 158
19.2 Choice revision 160
19.3 Revision by single sentences and Gärdenfors’
supplementary postulates 161
19.4 Mind opening contractions and normal revisions 165
20. Some comparisons with the AGM theory 174
  20.1 The AGM definitions of the contraction operation 174
  20.2 Contrasts 178
21. The modal logic of theory change 180
  21.1 Dynamic logic 181
  21.2 Propositional dynamic logic with expansion and minimal contraction programs 182

Introduction

This dissertation is a contribution to the study of relevant logics. Its emphasis is on applications. Such an emphasis, I believe, is timely. For the purely philosophical debate about the notion of entailment has reached a deadlock. It has issued on the one side in an elaborate classical epicycle\(^1\) and on the other side in a rich fundus of well-investigated alternatives to classical logic.\(^2\) The divide between these two sides is unlikely to become permeable by further reflections on the elusive notion of entailment or introspection of one’s linguistic intuitions about *if... then*... Progress, however, can perhaps be made by observing the contenders "in use" rather than *in vacuo*.

Almost coinciding with the decline of the entailment debate within the philosophical community is the increasing interest in non-classical logics among researchers in Artificial Intelligence (AI). It has become plain in recent years that for the solution of many problems in AI, classical logic is either not suited at all or an extremely cumbersome tool to use. Thus, in AI, alternatives to classical logic are now considered and evaluated free from the philosophical prejudices hardened in a seven decades spanning debate about "deviant" logics — non-classical logics suddenly get a "fair go".

The present dissertation attempts to take advantage of the open-minded attitude with which various logics are now considered in AI. Thus, the applications of relevant logics in Part Two of this dissertation are presented with a view to problems in AI. These problems fall under the heading of database theory. Chapter three offers some tools for reasoning about databases in a fixed state; chapter four treats the problem of database updating. In more traditional terms, however, these chapters contain also contributions to philosophical logic: chapter three presents some epistemic and deontic logics based on relevant logics, and chapter four is an exercise in the logic of theory change. The discussion in Part Two will frequently switch between philosophy and AI. Such a transfer of ideas, I believe, is beneficial to both disciplines.

Chapter one provides a grounding in the proof theory and semantics of relevant logics. We give axiomatic formulations of a group of logics, starting from a very weak system BM and proceeding to classical logic K via the comparatively strong relevant logics of Anderson and Belnap.

Introduction

(1975) and the semi-relevant systems RM ("Mingle") and RM3. All of these logics will be proved complete with respect to appropriate classes of model structures (frames) of the kind used in Routley, Meyer, et al. (1982). The aim of this chapter is to provide a self-contained completeness argument for all of the major relevant logics (and a few more) as a background to the following chapters. In presenting this argument I have benefited from Dunn's survey article on relevant logics (1986).

In chapter two we shall consider extensions of the systems presented in chapter one in a language including a unary modal operator. The resulting modal systems will be proved sound and complete with respect to two extensions of the semantics introduced in chapter one. The two extensions are, first, a Kripke-style semantics, modelling the modal operator by means of a binary accessibility relation, and, secondly, a Montague-Scott-style semantics in which the modal operator is modelled by means of a so-called neighbourhood function.

In Part Two, we shall put the systems of Part One to use. The modal logics of chapter two will be used in chapter three as a means to represent and reason about the static properties of theories of various kinds. We shall consider in some detail two kinds of theories: sets of sentences an agent is committed to accept as true at a particular point of time ("acceptance sets"), and sets of sentences an agent is committed to make true at a particular point of time ("norm sets"). As a result of these considerations, logics of acceptance (or commitment-to-believe) and of obligation will emerge. We shall refrain from enshrining in these logics idealising assumptions about acceptance sets and norm sets; in particular, we shall not assume that such sets are always consistent. The possibility, and indeed actuality, of inconsistent but non-trivial acceptance and norm sets will motivate the move towards epistemic and deontic logics based on a paraconsistent logic. The concern with representing correctly the deductive dependencies within acceptance sets and norm sets will motivate a move towards epistemic and deontic logics based on a relevant logic.

Chapter four focuses on certain dynamic aspects of theories. The study of the formal aspects of theory change - though a natural complement to the investigations of Tarski (1930) - has been curiously neglected for a long time. A beginning has only recently been made in the work of Alchourron, Gärdenfors and Makinson. Though squarely based within the framework provided by these three authors, the present contribution to the theory of theory change differs in a number of aspects
from their work. First, Alchourron, Gärdenfors and Makinson (AGM) consider changes of theories by one sentence at a time. I consider multiple changes: changes by sets of sentences at a time. Changes by single sentences will emerge as a special case of multiple changes, namely as changes by singleton sets of sentences. Secondly, AGM think of theories as sets of sentences closed under logical consequence; theories are thus rather amorphous objects. I think of theories as sets of sentences generated from a distinguished set of sentences (the base of the theory in question) by means of a logical consequence operation. As I shall argue in chapter four, the base of a theory does play an important role in changing a theory. Thirdly, a central concern for AGM is that changes to theories ought to be minimal: a changed theory should be as big a subset of the original theory as possible under the circumstances. I shall argue that minimality of change is a rule of thumb that may easily be overridden by other constraints on theory change. One such constraint — not recognised in the work of AGM — is that if a sentence B is in a theory just because A is in that theory, then B should not remain in the theory after A has been removed. I call this constraint on theory change "the filtering condition". Fourthly, for AGM, theories are closed under a consequence operation provided by classical logic. In view of classical theses like $A \rightarrow \neg A \rightarrow B$ and $A \rightarrow B \rightarrow A$, the change of inconsistent theories and the removal of logical truths from a theory receive a rather special treatment in AGM’s theory. The theory advanced in this dissertation will be more general: any one of the logics of chapter one may provide the consequence operation theories are closed under. However, as I shall argue in chapter four, only if theories are closed under a non-classical, relevant, consequence operation, does a satisfactory account of how inconsistent theories ought to change and how to remove logical truths from a theory emerge.

The chapters of Part Two complement each other in a straightforward sense: while chapter three provides a formal framework for reasoning about theories at a particular point of time, theories as they "move" along a time axis are the subject of formal investigations in chapter four. The formal tools employed in these chapters are, however, quite distinct. Whereas modal logics provide the background for chapter three, Tarski's theory of consequence operations is the unifying theory behind the considerations in chapter four. In the final section of this dissertation, an outlook on one way of bringing to bear modal logic on the theory of theory change will be given by employing the resources of dynamic logic in order to formulate a logic of theory change.
