ABSTRACT

Introduction: Pre-eclampsia is a common pregnancy condition affecting between 3% and 7% of women. Unfortunately, the exact pathophysiology of the disease is unknown and as such there are no effective treatments that exist notwithstanding prompt delivery of the fetus and culprit placenta. As many cases of pre-eclampsia occur in preterm pregnancies, it remains a significant cause of maternal and perinatal morbidity and mortality. Recently, in vitro and animal studies have highlighted the potential role of antioxidants in mitigating the effects of the disease. Melatonin is a naturally occurring antioxidant hormone and provides an excellent safety profile combined with ease of oral administration. We present the protocol for a phase I pilot clinical trial investigating the efficacy and side effects of maternal treatment with oral melatonin in pregnancies affected by preterm pre-eclampsia.

Methods and analysis: We propose undertaking a single-arm open label clinical trial recruiting 20 women with preterm pre-eclampsia (24⁺⁰–35⁺⁶ weeks). We will take baseline measurements of maternal and fetal well-being, levels of oxidative stress, ultrasound Doppler studies and other biomarkers of pre-eclampsia. Women will then be given oral melatonin (10 mg) three times daily until delivery. The primary outcome will be time interval between diagnosis and delivery compared to historical controls. Secondary outcomes will compare the baseline measurements previously mentioned with twice-weekly measurements during treatment and then 6 weeks postpartum.

Ethics and dissemination: Ethical approval has been obtained from Monash Health Human Research Ethics Committee B (HREC 13076B). Data will be presented at international conferences and published in peer-reviewed journals.

Trial registration number: ACTRN12613000476730 (ANZCTR).

INTRODUCTION

Pre-eclampsia is a multiorgan syndrome of pregnancy that manifests after 20 weeks

ARTICLE SUMMARY

Strengths and limitations of this study

- This trial is an appropriately designed pilot study with realistically set numbers to achieve easily measurable outcomes. Significant preparatory work has been conducted into the preliminary in vitro and animal studies to guide the trial design. The trial is the first of its type world-wide and if successful, will be able to direct future randomised controlled trials.
- Due to the nature of such a pilot study in pregnant women, the relatively small numbers of participants must act as their own pretreatment controls. It is predicted that this limitation will be overcome in subsequent trials that will be largely informed by the outcomes of this study.

gestation with new-onset hypertension alongside maternal end-organ dysfunction and/or intrauterine fetal growth restriction.¹ It affects between 3% and 7% of all pregnancies and is associated with substantial maternal and perinatal morbidity and mortality, with a significant proportion of fetal complications due to prematurity.² To date, the exact pathophysiology of pre-eclampsia is unknown, but early placental dysfunction plays a central role in all leading hypotheses.^{3–4} This placental dysfunction is thought to result in a local and systemic cascade of increasing oxidative stress in the mother, leading to endothelial dysfunction and subsequent end-organ consequences.

Placental hypoxia and reperfusion, as a consequence of abnormal placentation, result in oxidative stress leading to apoptotic and necrotic disruption of the syncytial structure.⁵ This disruption then results in the release of various factors and compounds

from the intervillous space into the maternal circulation that stimulate the production of proinflammatory cytokines, such as tumour necrosis factor α , interleukin 6 and antiangiogenic factors such as soluble fms-like tyrosine kinase 1 (sFlt1) and soluble endoglin (sEng).⁴ The resultant effect involves potentially widespread increased oxidative stress with antiangiogenic compromise to the maternal vasculature.

Melatonin (5-methoxy-*N*-acetyltryptamine) is an endogenous lipid-soluble antioxidant hormone produced primarily by the pineal gland in humans, providing circadian and seasonal timing cues. In addition, melatonin is also a powerful antioxidant, acting as a direct scavenger of oxygen free radicals, especially the highly damaging hydroxyl radical, and indirectly through upregulation of antioxidant enzymes including glutathione peroxidase, glutathione reductase, superoxide dismutase and catalase.^{6, 7}

Melatonin has several characteristics that make it an appealing treatment for use in pregnancy. Melatonin freely crosses the placenta⁸ and blood-brain barrier⁹ and has an excellent safety profile with no known adverse effects.^{10, 11} Reduced levels of melatonin are found in pregnant women with pre-eclampsia.¹² Placentae express receptors for melatonin¹³ and thus melatonin may protect against oxidative stress generated by the dysfunctional organ, thereby inhibiting the release of vasoactive factors responsible for the clinical syndrome of pre-eclampsia.

It has been previously shown that in an animal model of fetal growth restriction (FGR), melatonin administration reduced fetal hypoxia, improved neurodevelopment and decreased brain injury and oxidative stress in newborn lambs.¹⁴ In another published experiment the same group administered melatonin shortly before and during a short period of severe fetal asphyxia induced by umbilical cord occlusion at late-gestation. Melatonin prevented the formation of free radicals (hydroxyl radical) within the fetal brains and decreased lipid peroxidation and brain cell death.⁸ The protective effects of melatonin on ischaemia-reperfusion-induced oxidative damage to mitochondria in the rat placenta have also been published.¹⁵ Melatonin treatment improves placental function (fetal:placental weight ratio), improves birth weight and induces antioxidant enzymes in a rat model of maternal undernourishment, known to promote oxidative stress.¹⁶

Melatonin has been studied in several clinical trials in humans at varying gestations and for different purposes. Melatonin has been assessed in assisted reproductive technology where the quality of oocytes is important for the success of in vitro fertilisation (IVF). Melatonin is an important compound found in the follicular fluid that has been shown to be important for oocyte maturation and quality and has been suggested to improve pregnancy outcomes with IVF.¹⁷⁻¹⁹ To date, no babies born from melatonin-treated pregnancies have been shown to have any increase in abnormalities (Unfer V. personal

communication via email. In: Mockler J, ed., 2012). Melatonin has also been shown to upregulate antioxidant enzymes in human pregnancies leading to the conclusion that melatonin might provide an indirect protection against injury caused by reactive oxygen species as seen in pre-eclampsia, FGR and fetal hypoxia.²⁰

Melatonin does not have any acute pharmacological effects in the nervous or vascular systems, apart from its benign but active effect on sleep mechanisms.²¹ Mice that have received extremely high doses of up to 800 mg/kg melatonin did not have increased mortality and as such the median lethal dose could not be established.²¹ In humans, a phase II clinical trial conducted in the Netherlands administered 75 mg melatonin nightly to 1400 women over 4 years, with no serious side effects reported.²² The maternal no-adverse-effect-level (NOAEL) for melatonin has been found to be 100 mg/kg/day with the fetal NOAEL established at ≥ 200 mg/kg/day when administered to the mother. The maternal lowest observed adverse effect level toxicity was 200 mg/kg/day.²³

Rationale

Pre-eclampsia is a life-threatening condition for the mother as well as the baby affecting up to 7% of pregnancies.² Despite ongoing advancements in perinatal care, pre-eclampsia remains an incurable disease. Extensive animal studies demonstrate that the use of melatonin as an antioxidant in high-risk pregnancies is very promising. Melatonin readily crosses the placenta and does not harm the developing fetus, not even when administered in extremely high doses.²¹ This study aims to be the first human trial to assess the potential clinical and biochemical effects of melatonin in pregnancies complicated by preterm pre-eclampsia.

Aims

The aim of the trial is to establish whether melatonin will afford a clinical or biochemical benefit in women with early-onset pre-eclampsia. To test the hypothesis, we will pose the following research aims:

1. To determine the effect of daily maternal oral treatment with melatonin on the clinical outcomes of pregnancies affected by preterm pre-eclampsia.
2. To determine the effect of daily maternal oral treatment with melatonin on the oxidative stress response in the maternal, placental and fetal circulation in preterm pre-eclampsia.
3. To determine the effect of daily maternal oral treatment with melatonin on the clinical and biochemical measures of vascular function in the mother and fetus in preterm pre-eclampsia.

METHODS AND ANALYSIS

Study design

Phase I single-arm open label clinical trial.

Subjects

We plan to recruit 20 women with preterm pre-eclampsia. We will also perform a retrospective review of cases from the previous 24 months to use as historical controls for the primary outcome measure.

Study setting

We will recruit patients from the obstetric departments of Monash Health and Jessie McPherson Private Hospitals colocated in Melbourne, Australia over a 12-month period.

Sample size

This study is a proof-of-principle phase I trial and as such a power calculation has not been performed to determine sample size. The purpose of this trial is to establish appropriate outcome measures that can be used to calculate power for a future phase II randomised-controlled trial for the same intervention.

Inclusion criteria

1. Be at least 18 years of age
2. Be between 24⁺⁰ weeks' and 35⁺⁶ weeks' gestation
3. Have a singleton pregnancy
4. Have a diagnosis of pre-eclampsia (Society of Obstetric Medicine of Australia and New Zealand criteria¹)
5. Be considered capable of safely continuing the pregnancy for 48 h or more, as determined by the attending clinician
6. Obstetrician and neonatologist believe the fetus is likely to be viable
7. No major anomalies evident on the midtrimester morphology scan
8. Be capable of understanding the information provided, with use of an interpreter if required
9. Give written informed consent

Exclusion criteria

1. Eclampsia
2. Current use of melatonin
3. Contraindications to melatonin use including:
 - A. Hypersensitivity to melatonin or any of its derivatives
4. Imminent transfer to a non-trial centre due to unavailability of neonatal beds
5. Significant uncertainty regarding gestational age
6. Women to be treated as an outpatient
7. Use of any of the following medications:
 - A. Fluvoxamine
 - B. 5-Methoxypsoralen or 8-methoxypsoralen
 - C. Cimetidine
 - D. Quinolones and other CYP1A2 inhibitors

- E. Carbamazepine, rifampicin and other CYP1A2 inducers
- F. Zaleplon, zolpidem, zopiclone and other non-benzodiazepine hypnotics

Participant enrolment

The PAMPR trial will be introduced to potential trial participants identified from routine antenatal clinics, pregnancy assessment units and labour ward admissions within the trial institutions as identified by the principal investigator. Maternal and fetal assessments by the treating clinician combined with the results of blood tests will determine whether immediate delivery is essential for the survival and well-being of mother and baby. If the treating clinician considers delivery within 48 h as probable, the mother is not eligible for inclusion to the PAMPR trial. Absolute criteria for immediate delivery are not specified in this protocol and remain the responsibility of the attending clinician.

Where delivery within 48 h is considered unlikely, the women can be approached for consent to the PAMPR trial. The principal investigator will provide written information about the trial and answer any questions she or her relatives may have. The patient's written informed consent to participate in the trial must be obtained before recruitment and after a full explanation has been given of the treatment options and the manner of treatment administration. Ideally there should be a period of 24 h for a woman to consider whether she wishes to take part in the trial or not. However, it is considered clinically important to initiate treatment as soon as possible after the diagnosis of pre-eclampsia, therefore consent should be sought at the earliest opportunity, provided the investigator is reassured that the woman has fully understood the requirements of the trial.

Following admission to the hospital the trial medication will be written on the patient drug chart and administered through usual prescribing practices.

The historical controls for the primary outcome measure (interval from diagnosis to delivery) will be obtained through deidentified retrospective review of medical records from Monash Health over the previous 24-month period. These historical controls will be women diagnosed with preterm pre-eclampsia who meet the inclusion and exclusion criteria who underwent expectant management.

Table 1 Maternal biomarkers of oxidative stress

Samples collected at recruitment and then twice per week until delivery

Malondialdehyde	8-Isoprostane	Total antioxidant capacity
Superoxide dismutase	Melatonin	Haemeoxygenase

Table 2 Maternal biomarkers for pre-eclampsia**Samples collected at recruitment and then twice per week until delivery**

Soluble fms-like tyrosine kinase-1	Vascular endothelial growth factor	Highly sensitive C reactive protein
Soluble endoglin	Placental growth factor	Activin
von Willebrand factor	Neutrophil elastase	Platelet function tests

Intervention

Eligible women will receive melatonin (10 mg) tablets three times daily from recruitment until delivery.

Primary outcome

Interval in days from participant diagnosis with pre-eclampsia until delivery compared to historical controls.

Secondary outcomes

See tables 1–7 and box 1 for further details.

Proposed analyses

The length of gestation postrecruitment will be analysed using a t test.

The biomarkers will be analysed using a repeated measures analysis, including the baseline value as a covariate. For the primary analysis the treatment effect will be considered constant over time, secondary analyses will examine the possibility of a trend over time. Plots of mean score over time will be shown for clarification. Initially, the treatment effect will be assumed to be constant over time, but if time by treatment interaction is shown to be important by including this parameter in the model (the conventional level of $p=0.05$ will be used here) then further investigation into effects at differing time points will be made by analysing the least-square means as above. Plots of mean score over time will be shown for clarification.

All other continuous measures (clinical measures, etc) will be considered in the same manner as above (adjusting by baseline value if available). Dichotomous

Table 3 Markers of pre-eclampsia severity**Samples collected at recruitment and then twice per week until delivery**

Maternal blood pressure	Level of proteinuria	Haemoglobin
Platelet count	Liver transaminases	Renal function
Composite of pre-eclamptic symptoms: oedema, headache, visual disturbance, epigastric or left upper-quadrant pain		

Table 4 Markers of maternal morbidity**Samples collected at recruitment and then twice per week until delivery**

Serum creatinine equal to or >120 micromol/L	Proteinuria equal to or >5 g/24 h	Hypertension equal to or >170/110 mm Hg (despite Rx)
Signs of left ventricular failure	Eclampsia	Platelets <50×10 ⁹ /L
Disseminated intravascular coagulation	Cerebrovascular event	Liver transaminase equal to or >500 IU/L

outcomes (mortality, etc) will be presented as risk ratios, with a corresponding χ^2 test performed.

Apart from baseline value, no adjustments for covariates will be made in the first instance in any of the investigations. Treatment estimates will only be adjusted when subgroups are explored. Interaction between treatment and subgroup variables will be examined in a similar fashion as above by including the relevant parameters in the model. This will be performed in turn for each subgroup variable and adjusted estimates presented.

All tests are two sided and results will be presented as a point estimate along with 95% CIs.

Adverse events

Participants will be inpatients for the duration of the trial. As such, a senior obstetric clinician who will be in ongoing communication with the research team will see them daily. The principal investigator of the PAMPR trial will be contactable by telephone at all times in the case of an adverse event. Any serious adverse events that occur after joining the trial will be reported in detail in the participant's medical notes, followed up until resolution of the event and reported to the Monash Health Human Research Ethics Committee, Therapeutics Committee and Therapeutic Goods Administration of Australia's Office of Scientific Evaluation immediately or within 24–72 h.

Table 5 Ultrasound and Doppler measurements**At recruitment then twice per week (biometry every 2 weeks) until delivery**

Maternal brachial artery Biometry	Maternal uterine artery Amniotic fluid indices	Fetal morphology Placental location/anomalities
Fetal characteristics: heart rate, tone, breathing, movements		
Doppler velocimetry: umbilical artery, middle cerebral artery and ductus venosus		

Table 6 Pregnancy endpoints

Various timings		
Gestation at birth	Mode of birth	Placental histology/weight
Abnormal cardiotocogram	Labour analgesia/ anaesthesia	Duration of labour stages
Labour induction/augmentation	Duration of membrane rupture to birth	Group B streptococcus infection
Cord lactates: artery and vein	Presence of meconium liquor	Intrapartum lactates
Use of antihypertensives	Use of magnesium sulfate	Use of corticosteroids

Trial discontinuation or modification

Participants will be withdrawn from the trial at participant request or if they or their fetus suffer an unexpected serious adverse event as noted above. Worsening pre-eclampsia is within the natural history of the disease and as such will not be part of discontinuation criteria.

There will be no allowance for modification of the trial intervention.

Ethics and dissemination

Ethical approval has been obtained from the Monash Health Human Research Ethics Committee B (HREC 13076B). Data will be presented at international conferences and published in peer-reviewed journals. We will make the information obtained from the study available to the public through national bodies and charities.

DISCUSSION

If effective, we believe that treatment with melatonin could become standard of care for women with pregnancies complicated by preterm pre-eclampsia. The potential benefits to mother and baby would significantly reduce what is now a terrible burden of disease internationally. Treatment with this medication also has potential use in other pregnancy disorders such as FGR and hypoxia.

We do not, however, anticipate that this will be the final trial to determine whether further exploration of this area is worthwhile. We hope that the study will

Table 7 Neonatal outcomes

At birth		
Sex	Neonatal Apgar scores	Weight at birth
Length	Head circumference	Cord melatonin levels
Composite neonatal outcome: admission to NICU, duration of admission, need and duration of respiratory support, intraventricular haemorrhage, necrotising enterocolitis, abnormal neurology, mortality prior to discharge		

Box 1 Any serious adverse event

At any time during trial

generate sufficient evidence that melatonin may be effective; to support a funding application for a larger randomised controlled trial. Such a trial could be designed to test the hypothesis that melatonin treatment in preterm pre-eclampsia afforded superior and more cost-effective outcomes prioritised by consumer groups and clinicians than existing managements.
