In model studies towards the synthesis of harringtonolide, the construction of the tropone moiety via arene cyclopropanation was investigated. The installation of the lactone ring was accomplished by way of a Diels–Alder cycloaddition of various indenones and a-pyones. The incorporation of the key bridge methyl group and subsequent control of its stereochemistry is also outlined.

Introduction

The diterpenoid tropone, harringtonolide (3), was first isolated in North America from the seeds of Cephalotaxus harringtonia (Taxaceae) and its structure established by X-ray crystallography (Scheme 1).1 It was also isolated in China from C. hainanensis2,3 and found to have both anti-neoplastic and anti-viral properties, being active against Lewis Lung carcinoma, Walker carcinoma, Sarcoma-180, and L-1210, L-615 and P-388 leukaemias, as well as showing in vitro activity against influenza type A, Newcastle disease, Japanese B encephalitis and vaccinia viruses.4 Harringtonolide is a structurally rigid and congested molecule, consisting of seven adjacent stereocenters. Of particular interest is the presence of the cycloheptatrienone, or tropone, substructure since it is believed that this functionality is responsible for the biological activity of the compound.

While we have previously reported the successful synthesis of harringtonolide by way of an arene-cyclopropanation strategy, the approach had some inherent drawbacks.5–7 In particular, the relatively early formation of the reactive cycloheptatriene moiety and the need to carry out extensive manipulations in its presence had a deleterious impact on yields. It was clear from these difficulties that an improved route to harringtonolide was required. In this new scheme, the cyclopropanation–tautomerisation process would be effected at a much later stage so that fewer subsequent steps would be required. It was proposed that the lactone function be installed by means of a Diels–Alder cycloaddition reaction, while the ether ring would be established using cyclopropyl ring-opening chemistry (Scheme 2). The bulk of the harringtonolide skeleton would thus be in place prior to installation of the cycloheptatriene motif. While the initial [4 + 2] cycloaddition

Scheme 1 Previous synthesis of harringtonolide.

Scheme 2 Proposed route to harringtonolide.
between the indenone and the pyrone was likely to be problematic, the intramolecular cyclopropanation of the aromatic ring was of greater concern. This crucial step was not expected to be as favourable as the conversion of 1 to 2 in the previous total synthesis, given the different ring sizes and the potential for competing reactions, such as CH insertion at the benzylic position and/or ylide formation with the lactone carbonyl group.

Results and discussion

In order to study this key synthetic step and other aspects of the proposed route to harringtonolide, a series of model studies was initiated. From a geometrical perspective, diazoketone 10 was considered to be a good match for 7 (Fig. 1). This was supported by some preliminary computational calculations in which both molecules were overlaid for comparison purposes.

Fig. 1 Molecular geometry comparison.

5-Methoxyindanone (11),* prepared in 2 steps from commercially available m-methoxycinnamic acid, was treated with N-bromosuccinimide and triethylamine to afford indenone 12 in 69% yield (Scheme 3). Birch reduction of p-methoxyphenylacetic acid (13) followed by acidification and esterification afforded two isomers 14a and 14b in a 1.5 : 1 ratio.

Scheme 3 Reagents and conditions: i, NBS, reflux, CCl₄ then Et₃N, 85 °C, CCl₄, 69%; ii, Na, NH₃, −33 °C, THF; EtOH; iii, CH₃N₂, 0 °C, Et₂O, 67% overall (40% 14a; 27% 14b).

As indenone 12 was prone to dimerisation at high temperatures or in the presence of Lewis acids, high pressure activation was instead employed for the [4 + 2] cycloaddition reaction.⁹ When 12 and 14a were subjected to 19 Kbar for 24 h, cycloadduct 15 was obtained as a single product in 52% yield (Scheme 4).

Scheme 4 Reagents and conditions: i, 19 Kbar, rt, DCM, 52%; ii, KOH, rt, H₂O, EtOH, 96%; iii, LiEt₂BH, 0 °C, THF; iv, CH₃N₂, 0 °C, Et₂O, 90% overall; v, NIS, rt, THF, 75%; vi, AIBN, n-Bu₃SnH, reflux, THF, 95%; vii, KOH, rt, H₂O, EtOH, 93%; viii, NaH, rt, THF; ix, (COCl)₂, DMF, 0 °C, THF; x, CH₃N₂, 0 °C, Et₂O, 75% overall.

The endo stereochemistry was established by NOE differential spectral analysis of the observed correlations between the protons of the ethane bridge with the cyclopentanone ring protons. Methyl ester 15 was hydrolysed to afford acid 16, which was submitted to reduction with lithium triethylborohydride, followed by re-esterification with diazomethane. Following iodoetherification, tetrahydrofuran 19 was obtained in 75% yield over 3 steps from acid 16. The iodide was then subjected to reduction with tri-n-butyltin hydride furnishing methyl ester 20. Hydrolysis of 20 produced carboxylic acid 21 which was subsequently converted to diazoketone 10.

Having secured diazoketone 10, we reached the pivotal step for this initial model study. Based on our previous synthesis, rhodium mandelate was chosen as the catalyst for the initial test. Unfortunately, in our model system, these conditions provided CH-insertion compound 22 as the only isolable product (Scheme 5). A variety of alternative rhodium catalysts, such as Rh₂(OAc)₄ and Rh₂(acam)₄,¹⁰ were similarly unsuccessful. Copper(II) acetylacetone has proven to be an effective catalyst for the cyclopropanation of aromatic rings,¹¹ but it was unsuccessful in this instance. Finally, the desired product was obtained on treatment of diazoketone 10 with bis(N-tert-butylationaldiminato) copper(II).¹²

Having demonstrated that geometrical restraints still permitted cyclopropanation to take place, we next turned our attention to the installation of the lactone-ring framework of the harringtonolide molecule by means of a [4 + 2] cycloaddition reaction with a suitable pyrone (Scheme 6). A high pressure Diels–Alder reaction
intermediate range of reagents and conditions. Attempted iodoetherification of ring-opening was wholly unsuccessful, despite recourse to a wide quantitative yield. Unfortunately, subsequent mercury-mediated to be feasible (Scheme 7).

This journal is © The Royal Society of Chemistry 2007

between 12 and 24 furnished cycloadduct 25 as a single product in 72% yield with the desired endo stereochemistry being confirmed by spectral analysis and X-ray crystallography.

The next phase involved the construction of the internal framework of the molecule. This entailed the formation of an ether bond to introduce the tetrahydrofuran moiety and the incorporation of a bridge methyl group with the correct stereochemistry. Based upon previous work, the prospect of forming the tetrahydrofuran ring in harringtonolide by a process equivalent to 26 → 28 appeared to be feasible (Scheme 7).

Accordingly, ketone 25 was reduced to benzylic alcohol 29 in 77% yield (Scheme 8). A combination of diazomethane and a catalytic amount of palladium acetate afforded 30 in almost quantitative yield. Unfortunately, subsequent mercury-mediated ring-opening was wholly unsuccessful, despite recourse to a wide range of reagents and conditions. Attempted iodoetherification of intermediate 29 as per 18 → 19 merely resulted in oxidation of 29 to ketone precursor 25. Additional work would reveal the olefinic bond in 29 to be quite unreactive towards an array of different reagents, most likely a result of the electron-withdrawing nature of the adjacent lactone ring. In an effort to overcome this unexpected lack of reactivity, we decided to incorporate a methyl group into the 4-position of the pyrone, thereby obviating the need for the cyclopropyl ring-opening step entirely and with the additional benefit of increasing the electron density of the olefinic bond of the Diels–Alder adduct. Treating 24 with ethereal diazomethane afforded 32 in 82% yield (Scheme 9). When the newly prepared pyrone 32 and indenone 12 were subjected to high pressure, cycloadduct 33 was obtained. Elaboration of 33 posed an interesting challenge. Attack of an electrophilic reagent on the more exposed face of the olefinic bond would position the methyl group over the aromatic ring with the undesired endo stereochemistry. Accordingly, an indirect strategy was employed. Reduction of 33 to benzylic alcohol 34 followed by hydroboration–oxidation afforded diol 35 with the methyl substituent in the endo location. Oxidation of 35 with the Dess–Martin periodinane furnished diketone 36. Treatment of the diketone with a catalytic amount of DBU effected the epimerisation of 36 to the thermodynamic product 37 with the methyl group now adopting the requisite exo stereochemistry. The transformation of 36 to 37 was manifestly apparent from the 1H-NMR spectrum. The bridge methyl, which had appeared as a doublet at δ0.49 in 36, now had a chemical shift of δ1.35 in 37. This large downfield shift can be ascribed to the removal of the methyl group from the shielding effect of the aromatic ring. Reduction of diketone 37 afforded syn diol 38. Treatment of 38 with p-toluenesulfonic acid led to formation of the benzyl cation and trapping by the remaining hydroxyl to install the tetrahydrofuran ring system (31).

Demethylation of 31 was accomplished by the method of Fujita et al. using a combination of aluminium tribromide and tetrahydrothiophene (Scheme 10). Compound 39 was then converted to the corresponding acid chloride which was immediately reduced to primary alcohol 40. Following oxidation of the carbonyl to 41, the aldehyde was added to an excess of the methoxymethylene ylide thereby producing (Z)-methylenol ether 42 in 58% yield. The enol ether was hydrolysed to the homologated aldehyde 43 and then oxidised to carboxylic acid 44. The acid chloride, generated by addition of the Vilsmeier reagent to a benzene solution of 44, was converted in situ to diazoketone 45 with ethereal diazomethane. A strong band at 2106 cm⁻¹ in the IR spectrum was characteristic of

the asymmetric diazo stretch while a molecular ion of m/z 354 was accompanied by a fragmentation pattern showing loss of nitrogen to produce a peak at m/z 328.

Heating diazoketone 45 in the presence of bis(N-tert-butylsalicyldiminate) copper(II) resulted in a complex mixture of products. Unfortunately, it was evident from the 1H-NMR spectrum that no arene cyclopropanation had taken place. Neither the use of Cu(acac)₂ nor of Rh(OAc)₂ was successful - both catalysts merely produced a complex mixture of aromatic compounds. The most likely explanation for the failure of the arene cyclopropanation sequence involves carbonyl ylide formation with the lactone ring.

Masking of carbonyls as ortho acetals has previously been used to circumvent ylide formation. Accordingly, acid 44 was protected as the methyl ester 46 using diazomethane. Regrettably, we were unable to transform 46 to the corresponding ortho acetal derivative. Even powerful reagents such as the Meerwein salt method or Noyori’s method failed to effect the desired transformation.

At this point, we opted to revise our synthetic approach. First, we would incorporate the C8 methyl, which corresponds to the tropone methyl substituent, into the indenone intermediate. Secondly, we would seek to increase the reactivity of the olefinic bond in the cycloadduct by reducing the carboxyl group at an early stage in the synthetic plan. Finally, we would investigate the feasibility of blocking unwanted ylide formation by reduction of the lactone and subsequent protection of the resultant lactol.

Demethylation of 32 to carboxylic acid 47 by in situ generation of trimethylsilyl iodide proceeded well (Scheme 11). Meanwhile, bromination of indanone 48, a known compound, and subsequent elimination afforded indenone 4 in 63% yield. Once again, a high pressure Diels–Alder reaction between 47 and 4 furnished cycloadduct 49 with the required regio- and stereochemistry. Compound 49 was converted to the corresponding acid chloride and then reduced to carbinol 50. This alcohol was subsequently protected as the tert-butyldimethyl silyl ether 51 in good yield.

Applying the previously established methodology, ketone 51 was reduced to the benzylic alcohol 52 and, following hydroboration-oxidation of the olefinic bond, diol 53 was oxidised to diketone 54 (Scheme 12). Treatment of 54 with a catalytic amount of DBU afforded epimer 55 in 98% yield. Interestingly, while the epimerisation of 36 to 37 had provided a 1 : 3 ratio of endo : exo products, conversion of 54 to 55 went to completion with no starting material remaining. This unexpected result is presumably due to the bulky TBDMs ether side chain, which favours the thermodynamic product through steric interaction. Indeed, MM2 calculations suggest a 2.01 kcal mol⁻¹ energy difference between...
Finally, we proposed reducing the lactone to the corresponding lactol, followed by masking of the resultant hydroxyl with a bulky protecting group, namely a TBDMS ether. The reason for the introduction of this group was twofold - first, to block any reaction between the carbenoid and the free hydroxyl and secondly, to direct the carbenoid towards the aromatic ring. Previous studies on gibberellin intermediates had demonstrated that a DIBAL reduction could be conducted in the presence of a dichloroacetate protecting group. With this information in mind, we returned to substrate 56 and the TBDMS ether was cleaved with tetrabutylammonium fluoride to afford the primary alcohol 57, which was then reprotected as the dichloroacetate 58 (Scheme 13). Reduction of 58 with DIBAL at $-40^\circ$C furnished the desired hemiacetal 59 in 57% yield. Protection of the hemiacetal as the TBDMS ether 60 proceeded readily while subsequent hydrolysis of the acetate ester furnished advanced intermediate 61.

**Conclusions**

These preliminary model studies have allowed us to investigate the feasibility of a more concise route to the complex diterpenoid, harringtonolide. While our initial studies demonstrated that the geometry of the molecule is suitable for arene-cyclopropanation purpose, we have also uncovered a number of unforeseen obstacles. In particular, the low reactivity of the olefinic bond of the Diels–Alder cycloadduct and the propensity of the $\alpha$-diazoketone intermediate to undergo unwanted ylide formation with the lactone ring moiety were problematical. We have successfully incorporated the bridge methyl substituent via the pyrone starting material and have controlled its stereochemical orientation in subsequent work.

Finally, we have modified the chemistry of the lactone ring and incorporated a bulky protecting group in the expectation of blocking ylide formation and directing cyclopropanation towards the aromatic ring. We hope to report on our work on the remaining steps (Scheme 14) and the completion of this synthesis in due course.
Experimental

General experimental

Starting materials and reagents used in reactions were obtained commercially and were used without purification, unless otherwise indicated. Flash chromatography was conducted with Merck Kieselgel 60 silica gel as the adsorbent. Proton nuclear magnetic resonance (1H NMR) spectra were recorded on a Varian Gemini 300 spectrometer at 300 MHz. Carbon-13 nuclear magnetic resonance (13C NMR) were recorded on Varian Gemini 300 spectrometer at 75.5 MHz. Infrared (IR) spectra (νmax) were recorded on a Perkin-Elmer 683 Infrared spectrophotometer in KBr plates. Low resolution EI mass (LRMS) spectra (70 eV) and high resolution accurate mass measurements (HRMS) were recorded on a VG Autospec double focussing mass spectrometer. Melting points (mp) were recorded on a Reichert hot-stage and are uncorrected. Microanalyses were conducted by the Australian National University Analytical Services Unit, Canberra.

5-Methoxyindenone (12)

N-Bromosuccinimide (356 mg, 2 mmol) was added to a solution of the indanone 11 (324 mg, 2 mmol) in carbon tetrachloride (50 ml). The resulting suspension was stirred at 85 °C for 2 hours. Triethylamine (1 ml) was added, and the resulting suspension was stirred at reflux with irradiation for 2 hours. The reaction mixture was then subjected to high pressure (19 Kbar) for 2.5 h. The resulting mixture was acidified with 1 M HCl (pH = 5), and then extracted with ethyl acetate (4 × 80 ml). The combined organic phase was washed with water (2 × 40 ml), brine (40 ml) and dried over sodium sulfate. After filtration, the solvent was removed under reduced pressure and the residue was treated with ethereal diazomethane at 0 °C. After removal of the solvent, the residue was purified by flash chromatography on silica gel (petroleum ether 40–60 °C; ethyl acetate 5:1) to afford an inseparable mixture of the methyl esters (14a: 14b = 1.5 : 1; 2.46 g, 67%) as a pale yellow oil.

Methyl-2-(1'-methoxycyclohexa-1',3'-dienyl)ethanoate (14a) and methyl-2-(1'-methoxycyclohexa-1',4'-dienyl)ethanoate (14b)

Liquid ammonia (150 ml) was added to a solution of 2-(4'-methoxybenzene)ethanoic acid (13) (3.32 g, 20 mmol) in ethanol (10 ml) and THF (20 ml). Sodium (metal, 3.2 g, 140 mmol, 7 eq.) was added in small pieces over a period of approximately 1 h until the blue colour persisted for 4 min. The ammonia was allowed to evaporate overnight. Ice (200 g) was added to the residue. The resulting mixture was acidified with 1 M HCl (pH = 5), and then extracted with ethyl acetate (4 × 80 ml). The combined organic phase was washed with water (2 × 40 ml), brine (40 ml) and dried over sodium sulfate. After filtration, the solvent was removed under reduced pressure and the residue was treated with ethereal diazomethane at 0 °C. After removal of the solvent, the residue was purified by flash chromatography on silica gel (petroleum ether 40–60 °C; ethyl acetate 5:1) to afford an inseparable mixture of the methyl esters (14a: 14b = 1.5 : 1; 2.46 g, 67%) as a pale yellow oil.

Methyl-2-(1'-methoxycyclohexa-1',3'-dienyl)ethanoate (14a), δH (300 MHz, CDCl3) 7.69 (1H, d, J = 6.0 Hz, H−C=C), 4.85 (1H, d, J = 6.1 Hz, H−C=C−OCH3), 3.62 (3H, s, OCH3), 3.52 (3H, s, OCH3), 3.01 (2H, m), 2.72 (2H, m), 2.25 (2H, s × 2).

Methyl-2-(1'-methoxycyclohexa-1',4'-dienyl)ethanoate (14b), δH (300 MHz, CDCl3) 5.50 (1H, m, H−C=C), 4.55 (1H, m, H−C=C−OCH3), 3.62 (3H, s, OCH3), 3.49 (3H, s, OCH3), 2.96 (2H, m), 2.72 (2H, m), 2.25 (2H, s × 2 H). The indenone 12 (160 mg, 1 mmol) and a mixture of dienes 14a and 14b (364 mg, 2 mmol) were dissolved in dichloromethane (1 ml) under nitrogen. The reaction mixture was then subjected to high pressure (19 Kbar) for 2.5 h. The resulting mixture was purified by flash chromatography on silica gel (petroleum ether 40–60 °C; ethyl acetate 5:1) to afford an inseparable mixture of the methyl esters (14a: 14b = 1.5 : 1; 2.46 g, 67%) as a pale yellow oil.
The methyl ester \( 15 \) (410 mg, 1.2 mmol) and potassium hydroxide (1.01 g, 18 mmol, 15 eq.) were dissolved in ethanol (25 ml) and water (5 ml). After addition, the reaction mixture was stirred at room temperature under darkness overnight (14 hours), then diluted with ethyl acetate (100 ml) and brine (30 ml). The aqueous phase was extracted with ethyl acetate (20 ml). The combined organic phase was dried over sodium sulfate. After filtration, the solvent was removed under reduced pressure to afford the methyl ester \( 16 \) (380 mg, 96.4%), after recrystallisation from ethyl acetate (20 ml) was cooled to 0\(^\circ\)C. Ice (100 g) was added, then acidified with 1 M HCl (20 ml) and extracted with chloroform (5 x 25 ml). The combined organic phase was dried over sodium sulfate. After filtration, the solvent was removed under reduced pressure and the residue was purified by flash chromatography on silica gel (petroleum ether 40–60 °C : ethyl acetate = 2 : 3 → 0 : 1 → DCM : MeOH = 10 : 1 → 5 : 1) to afford the acid \( 16 \) (380 mg, 96.4%), after recrystallisation from ethyl acetate, as colourless needles; mp 221–222\(^\circ\)C.

The methyl ester \( 15 \) (282 mg, 0.56 mmol) and azobisisobutyronitrile (262.3 mg, 0.56 mmol) were dissolved in anhydrous THF (30 ml). The resulting solution was stirred at room temperature under darkness overnight (60 min). After removal of the solvent, the residue was purified by flash chromatography on silica gel (petroleum ether 40–60 °C : ethyl acetate = 5 : 1 → 2 : 1 → 1 : 1) to afford the product \( 19 \) (282 mg, 75.3%) as a colourless oil. Recrystallisation from ethyl acetate solution afforded white crystals; mp 116–117 °C (from EtOAc).

The alcohol \( 20 \) (275 mg, 0.8 mmol) and \( n \)-iodosuccinimide (225 mg, 1 mmol) were dissolved in THF (25 ml). The resulting solution was stirred at room temperature under darkness overnight (4 hours), then diluted with ethyl acetate (100 ml) and washed with 5% sodium thiosulfate (Na\(_2\)S\(_2\)O\(_3\)) aqueous solution (2 x 30 ml) and brine (30 ml). The aqueous phase was extracted with ethyl acetate (20 ml). The combined organic phase was dried over sodium sulfate. After filtration, the solvent was removed under reduced pressure and the residue was purified by flash chromatography on silica gel (petroleum ether 40–60 °C : ethyl acetate = 5 : 1 → 2 : 1 → 1 : 1) to afford the product \( 19 \) (282 mg, 75.3%) as a colourless oil. Recrystallisation from ethyl acetate solution afforded white crystals; mp 116–117 °C (from EtOAc).

The alcohol \( 20 \) (275 mg, 0.8 mmol) and \( n \)-iodosuccinimide (225 mg, 1 mmol) were dissolved in THF (25 ml). The resulting solution was stirred at room temperature under darkness overnight (4 hours), then diluted with ethyl acetate (100 ml) and washed with 5% sodium thiosulfate (Na\(_2\)S\(_2\)O\(_3\)) aqueous solution (2 x 30 ml) and brine (30 ml). The aqueous phase was extracted with ethyl acetate (20 ml). The combined organic phase was dried over sodium sulfate. After filtration, the solvent was removed under reduced pressure and the residue was purified by flash chromatography on silica gel (petroleum ether 40–60 °C : ethyl acetate = 5 : 1 → 2 : 1 → 1 : 1) to afford the product \( 19 \) (282 mg, 75.3%) as a colourless oil. Recrystallisation from ethyl acetate solution afforded white crystals; mp 116–117 °C (from EtOAc).

The alcohol \( 20 \) (275 mg, 0.8 mmol) and \( n \)-iodosuccinimide (225 mg, 1 mmol) were dissolved in THF (25 ml). The resulting solution was stirred at room temperature under darkness overnight (4 hours), then diluted with ethyl acetate (100 ml) and washed with 5% sodium thiosulfate (Na\(_2\)S\(_2\)O\(_3\)) aqueous solution (2 x 30 ml) and brine (30 ml). The aqueous phase was extracted with ethyl acetate (20 ml). The combined organic phase was dried over sodium sulfate. After filtration, the solvent was removed under reduced pressure and the residue was purified by flash chromatography on silica gel (petroleum ether 40–60 °C : ethyl acetate = 5 : 1 → 2 : 1 → 1 : 1) to afford the product \( 19 \) (282 mg, 75.3%) as a colourless oil. Recrystallisation from ethyl acetate solution afforded white crystals; mp 116–117 °C (from EtOAc).

The methyl ester 20 (172 mg, 0.5 mmol) and potassium hydroxide (560 mg, 10 mmol, 2 eq.) were dissolved in ethanol (12 ml) and water (3 ml). The reaction mixture was stirred at room temperature for 6 h. Ice (80 g) was then added and the mixture was acidified with 1 M HCl (15 ml) and extracted with chloroform (5 × 20 ml). The organic phase was dried over sodium sulfate. After filtration, the solvent was removed under reduced pressure and the residue was purified by flash chromatography on silica gel (ethyl acetate) to afford the acid 21 (153 mg, 92.7%), after recrystallisation from ethyl acetate, as colourless needles; mp 189–190 °C (from EtOAc); found: C, 68.65%; H, 6.67%. Calc. for C_{19}H_{22}O_{5}: C, 68.97%; H, 6.71%; V_{m_rms/cm^{-1}} 3500 (OH), 3000 (ArH), 2950 (CH), 1730 (C=O), 1248 (ArOCH), 1200 (C=O), 1085 (ArOCH), 1030 (ArOCH); δ_{H} (300 MHz, CDCl₃) 7.35 (1H, d, J = 8.2 Hz, H-8), 6.92 (1H, d, J = 2.2 Hz, H-5), 5.24 (1H, d, J = 5.1 Hz, H-9), 5.20 (1H, br s, CH₃N), 4.12 (1H, d, J = 7.2 Hz, H-2), 3.77 (3H, s, CH₃O-C₆), 3.47 (1H, d, J = 8.8 Hz, H-4a), 3.28 (3H, s, CH₃O-C₁), 3.01 (1H, dd, J = 1.5, J = 5.1 Hz, 8.8 Hz, H-9a), 2.38 (1H, d, J = 14.4 Hz, H-12a), 2.04 (1H, d, J = 14.4 Hz, H-12B), 1.96 (3H, m), 1.64 (2H, m), 1.20 (1H, dd, J = 2.5, J = 14.7 Hz, H-3b); δ_{C} (75 MHz, CDCl₃) 193.45 (CO), 159.94 (C₆), 146.12 (C₄b), 136.98 (C₈a), 125.95 (C₈), 113.14 (C₇), 112.24 (C₅), 84.04 (C₉), 83.14 (C₁), 77.64 (C₂), 55.41 (CH₃O-C₆), 55.18 (CH₃O-C₁), 51.83 (CH₃O-C₁), 51.18 (C₄a), 50.02 (C₉a), 44.48 (C₁₂), 41.57 (C₃), 35.12 (C₁₀), 32.28 (C₄), 19.08 (C₁₁); m/z 354 (M⁺, 4%), 326 (100), 298 (51), 283 (20), 270 (17), 251 (35), 241 (84), 223 (44), 202 (58), 171 (37), 158 (52), 146 (76), 128 (33), 102 (34), 91 (20), 71 (27).

(3aSR,5SR,5aRS,6RS,10bRS,10cRS,10eRS)-5,9-Dimethoxy-6,11-epoxy-2-oxo-2,3,3a,4,5,5a,6,10b-octahydro-5,10c-ethano-1H-cyclopenta[f]-[1H]-fluorene (22)

A solution of diazoketone 10 (3 mg, 0.0085 mmol) in dichloromethane (2 ml) was added to a suspension of Rh₃ (mandelate), (0.2 mg) in dichloromethane (2 ml) at reflux. After the addition, the resulting mixture was stirred at reflux for a further 10 min. One drop of DBU was added and stirring was continued for another 2 min. After removal of the solvent, the residue was purified by flash chromatography on silica gel (ethyl acetate) to afford an inseparable mixture of C–H insertion products (3aα: 3aβ = 2:1; 1.3 mg, 46.9%) as a colourless oil.

Major isomer. δ_{H} (300 MHz, CDCl₃) 7.38 (1H, d, J = 8.3 Hz, H-7), 6.82 (1H, dd, J = 2.3, J = 8.3 Hz, H-8), 6.62 (1H, d, J = 2.3 Hz, H-10), 5.27 (1H, d, J = 5.4 Hz, H-6), 4.34 (1H, d, J = 8.5 Hz, H-11α), 3.79 (3H, s, CH₃O-C₉), 3.33 (3H, s, CH₃O-C₅), 3.11 (1H, dd, J = 1.8, J = 8.7 Hz, H-10b), 3.02 (1H, ddd, J = 1.7, J = 5.4, J = 8.7 Hz, H-5a), 2.70–2.55 (2H, m), 2.45–2.30 (2H, m), 2.25 (1H, m), 1.93–1.60 (3H, m), 1.54 (1H, ddd, J = 2.0, J = 8.5, J = 13.9 Hz, H-12a).

Minor isomer. δ_{H} (300 MHz, CDCl₃) 7.38 (1H, d, J = 8.3 Hz, H-7), 6.82 (1H, dd, J = 2.3, J = 8.3 Hz, H-8), 6.62 (1H, d, J = 2.3 Hz, H-10), 5.36 (1H, d, J = 5.4 Hz, H-6), 4.13 (1H, dd, J = 1.7, J = 8.5 Hz, H-11α), 3.79 (3H, s, CH₃O-C₉), 3.32 (3H, s, CH₃O-C₅), 3.22 (1H, dd, J = 1.8, J = 8.7 Hz, H-5a), 3.16 (1H, ddd, J = 1.7, J = 5.4, J = 8.7 Hz, H-5a), 2.90–1.50 (9H, m).
A solution of the diazoketone 10 (21 mg, 0.06 mmol) in toluene (5 ml) was added dropwise to a solution of copper(II) bis(N-tert-butylsalicylaldiminato) (3 mg) in toluene (3 ml) at reflux. After the addition, the resulting mixture was stirred at reflux for a further 15 min. The reaction mixture was cooled to room temperature and one drop of DBU was added. After stirring for 30 min at 40 °C (oil bath), the solvent was removed and the residue was purified by flash chromatography on silica gel (petroleum ether 40–60 °C : ethyl acetate = 1:1 → 1:5 → 0:1) to afford the product 23 (5.8 mg, 30%) as a yellow oil; \( \text{v}_{\text{max}} \text{cm}^{-1} \) 2924 (CH), 1730 (C=O), 1660 (C=O), 1245 (CC=OC); \( \delta \) (H, d, J = 3.7 Hz, H-4), 4.07 (1H, d, J = 3.7 Hz, H-3), 3.01 (1H, m, H-5), 3.50 (3H, s, CHO-C7), 3.30 (3H, s, CH2 CO-C3), 3.11 (1H, d, J = 10.2 Hz, H-10b), 3.01 (1H, m, H-5a), 2.87 (1H, dd, J = 3.8, J = 9.9 Hz, H-3a), 2.10–1.85 (3H, m), 1.70–1.45 (6H, m); \( \delta \) (75 MHz, CDCl3) 148.49 (C4a), 143.76 (C10c), 130.04 (C8a), 120.77 (C8), 94.75 (C6), 84.55 (C4), 83.67 (C3), 78.32 (C2), 55.82 (CH2 O-C7), 50.29 (C10b), 49.39 (CH2O-C3), 47.43 (C10a), 45.57 (C3a), 38.69 (C12), 34.16 (C11), 33.99 (C10), 32.00 (C5), 19.18 (C1); m/z 326 (M+, 94%), 325 (100), 310 (7), 295 (8), 281 (14), 265 (20), 249 (44), 237 (20), 224 (65), 211 (24), 178 (10), 167 (7), 158 (23), 139 (9), 128 (11), 115 (18), 91 (5), 71 (10).
