"A Great Deal of Sickness"

Introduced diseases among the Aboriginal People of colonial Southeast Australia 1788-1900

Peter J. Dowling
January 1997

A thesis submitted for the degree of Doctor of Philosophy of the Australian National University, Canberra

Abstract

Palaeopathological studies have sought to build up a picture of Australian Aboriginal health before European settlement in 1788, and epidemiological studies of Aboriginal health in the twentieth century are now legion. But, despite a growing body of literature on Aboriginal history in the intervening colonial period, this remains an under-studied period from the viewpoint specifically of Aboriginal health. This thesis is a contribution to filling that gap through an examination of documentary and skeletal evidence on the changing bio-medical situation experienced by Aboriginal populations of Southeast Australia from 1788 to 1900.

This thesis examines one of the major biological components of this change - the diseases that were introduced into Australian Aboriginal populations during the process of colonisation. The epidemiology, timing, diffusion of diseases are considered with specific attention given to infectious and respiratory diseases that were responsible for causing major epidemics of morbidity and mortality.

A medical model for the contact period in the late 18th and 19th centuries is proposed. This model considers three major stages in the disease environment of Aboriginal populations in Southeast Australia: a pre-contact stage with endemic pathogens causing chronic diseases and limited epidemics, an early contact stage where introduced exotic human diseases cause severe epidemics of infectious and respiratory diseases among Aboriginal populations, and a third stage where remaining Aboriginal populations were institutionalised on government and mission settlements and were subjected to a high level of mortality from the introduced diseases.

The major epidemic diseases during the early contact stage were smallpox, syphilis, tuberculosis, influenza, and measles. Each of these diseases were responsible for excessive morbidity and mortality. During the period of institutionalisation infectious and respiratory diseases were responsible for over 50% of recorded deaths on 8 separate Aboriginal settlements in Southeast Australia. The major diseases recorded as causes of death were tuberculosis, bronchitis, pneumonia, diarrhoea and dysentery.

Aboriginal and non-Aboriginal Australian infant mortality rates are calculated to provide an indicator to compare the state of health of the two populations. Aboriginal rates were high when compared to the non-Aboriginal populations of Victoria and South Australia. The rates reveal a substantial health differential between Aboriginal and non-Aboriginal populations. Aboriginal infant mortality has improved into the latter quarter of the twentieth century but the corresponding improvement in non-Aboriginal infant mortality has been at a much higher rate. The gap between the health status of each has widened rather than narrowed over the last one hundred years.
Acknowledgments

When I first began this project I was warned by several colleagues that finding nineteenth century information regarding the impact of introduced diseases on Aboriginal populations would be difficult. The sources of information I would need, if they existed at all I was warned, would most likely be scattered throughout archival texts in several capital cities and much of it would not be readily obtainable through current archival referencing aids. They were correct. Much of the material obtained came after seemingly endless days of searching through bundles of files, often without any success, in the libraries and public records offices of five capital cities. In order to find them, understand them, use them in the way I wished, cope with all the inevitable setbacks, and finally put them all together in what I hope is a coherent story required the help of many people.

At the top of the list is my wife Dianne. Once again she had to cope with this thing called a thesis which invaded her life just as much as it did mine. Without her understanding, help in the archives, and support throughout the good times and the bad times, this thesis would never have been written.

My supervisory team require a large thank you for their guidance, criticism, and encouragement throughout the processes of research, analysis, writing and rewriting. Dr Robert Attenborough bore the biggest burden and his kind help, together with a role of devil's advocate and administrator were greatly appreciated. Professor Isabel McBryde's depth of knowledge of Australian Aboriginal history helped me understand the material all the better. I also thank her for those 'spiky bits'. Dr Alan Thorne's advice, particularly in the initial stages, was appreciated. On the medical side I thank Dr Bryan Furnass who had just retired from the campus medical centre only to find a more demanding patient with a chronic disease we eventually called thesisitis. His advice, interest and encouragement helped me over many hurdles. Thanks also go to Professor Richard Wright who advised me on the use and interpretation of multivariate statistics.

Big thanks go to those who volunteered to read and comment on various drafts of the thesis; John Harrison, Dr Judith Littleton, Dr David Cameron and Dr Mary Jane Mountain. I was only too glad to accept their help.

I would also like to thank Dr Barbara Tyler from the Wanniassa Medical Centre, who always showed interest in the project during my medical checkups. I spent several extended consultations with her discussing the symptoms and epidemiology of infectious and respiratory diseases, none of which were the reason for my visits.

Another big thanks goes to Peter Figg with whom I met almost every Wednesday for lunch and a precious pint of Guinness. I was often asked to explain my work in elementary terms thereby making my own perceptions all the more clearer.

And then there was the extended family. My son Michael and daughter-in-law Deborah who patiently listened to me as I begged for help after creating another glitch on my computer; David, Angela, Ashley Jean and Marcus for regularly bringing me noisy, chaotic but totally
enjoyable diversions; the South Australians: Joan and Bill Johns, Beverley Dowling, Gilly and Beth Dowling, Colin and Glad Dowling and all those of the following generation for the interest they took and the support they gave; Geoff and Barb Banks for their long friendship and concern; the Tasmanian in-laws Colin and Marj Walters who have come to appreciate the Aboriginal past by farming the land surrounding the Little Swanport midden; Judy Belbin who showed more concern for the writer than the thesis; Chris and Bob Robson who, although not always here, were never really far away; and the Harrison clan with whom we spent many a pleasant afternoon and evening.

I owe a special thanks to Dr Judith Littleton and Dr Jan Klaver who have been my helpers and critics, but most of all my friends for over a decade.

I must also thank Dr Goran Şevo to whom I often turned for advice on diseases, their symptoms, epidemiology, and diagnosis even though he may have been on the other side of the world or just the other side of the room.

I also value the friendship of my other colleagues Dr Aubrey Parke, Dr Keiko Tamura, Dr Mark Hudson, Dr Kate Stockhausen, Dr David Cameron, Tom Knight, Dr Ben Evans, and Dr Judith Caton with whom I shared room LG23 at one time or another. I thank them for having the grace, while in the midst of their own theses, for listening to me.

For those many days and evenings spent in archival rooms in five cities I must thank the librarians, archivists and library staff, whose names I never knew, for guiding me through the collections.

And finally Taia whom I think approved of this thesis only because it meant I was often at home and the house was warm on those cold Canberra days.

Go raibh mile maith agat.
