(Received 6 October 2010; revised manuscript received 31 May 2011; published 9 August 2011)

We obtain an analytical equation of state for one-dimensional strongly attractive Fermi gases for all parameter regimes in current experiments. From the equation of state, we derive universal scaling functions that control whole thermodynamical properties in quantum critical regimes and illustrate the physical origin of quantum criticality. It turns out that the critical properties of the system are described by those of free fermions and those of mixtures of fermions with masses \( m \) and \( 2m \). We also show how these critical properties of bulk systems can be revealed from the density profile of trapped Fermi gases at finite temperatures and can be used to determine the \( T = 0 \) phase boundaries without any arbitrariness.

I. INTRODUCTION

Quantum critical phenomena are associated with phase transitions at zero temperature as the parameters of the system are varied. They are among the most challenging problems in condensed-matter physics, since quantum fluctuations couple strongly with thermal fluctuations in this regime. From this viewpoint, one-dimensional (1D) integrable models, exhibiting phase transitions at \( T = 0 \), are particularly valuable as they can be solved exactly using the Bethe ansatz (BA) [1]. These exact solutions will illustrate the microscopic origin of their quantum criticality and will provide advances in the studies of quantum critical phenomena and universal scaling theory at quantum criticality. On the other hand, recent advances in cold-atom experiments have provided a highly controlled environment for studying 1D quantum gases in practically all physical regimes, thus, allowing one to study the predictions of the BA.

Despite much work on 1D Fermi gases [2,3], there are few studies on quantum criticality using BA solutions. This is mainly because the thermodynamic properties of integrable models at finite temperatures are notoriously difficult and present formidable challenges in theoretical and mathematical physics. On the other hand, the bosonization field-theory prediction [4] on the low-temperature thermodynamics of 1D many-body systems merely relies on the low-lying excitations that do not give proper thermal potentials in the quantum critical regime. Here, we first present these studies of quantum criticality and scaling functions for 1D Fermi gases with an attractive \( \delta \)-function interaction, which is known to have many interesting phases at \( T = 0 \) [5–11], including the so-called Fulde-Ferrell-Larkin-Ovchinnikov-(FFLO)-like [12] phase. Our purpose is multifold: (I) We present exact analytic expressions of the pressure, the equation of state, and the other thermodynamic quantities in the strongly interacting regime that are valid over all parameter regimes in the current experiments [13]. These expressions will be useful to compare with the current results and to examine the features of the model confirmed in the experiment [13]. (II) We show that the pressure \( P \) takes on an intuitive form. It can be regarded as a sum of the pressures of free fermions and hard-core bosons plus interactions of clusters of these entities: two clusters, three clusters, etc. (III) We show that, at criticality, the pressure of this system reduces to that of free fermions or mixtures of them. The criticality of the FFLO phase, when entered from different phases, is characterized by the latter. (IV) We show that, by using the scaling properties of the density of each spin component in the quantum critical region, one can map out the \( T = 0 \) phase diagram of a bulk system using the \( T > 0 \) density data of a trapped gas as recently pointed out by one of us [14]. We show how quantum criticality can help determine the presence of the FFLO-like phase, the universal Tomonaga-Luttinger liquid (TLL), and how the entire \( T = 0 \) phase diagram of the bulk system can be mapped out from the finite-temperature nonuniform density profile of different spin components in experiments. This approach to quantum criticality will open the study of quantum critical phenomena of spinor Fermi and Bose gases with higher spin symmetries.

II. EXACT \( T = 0 \) PHASE BOUNDARIES OF ATTRACTIVE 1D FERMI GASES

The Hamiltonian of a 1D Fermi gas with an attractive \( \delta \)-function interaction is

\[
\mathcal{H} = \frac{\hbar^2}{2m} \int dx (\partial \psi_\sigma^\dagger \partial \psi_\sigma + c \psi_\uparrow^\dagger \psi_\downarrow^\dagger \psi_\downarrow \psi_\uparrow),
\]

where

\[
N = \sum_\sigma \int dx \, \psi_\sigma^\dagger \psi_\sigma, \quad M = \frac{1}{2} \int dx (\psi_\uparrow^\dagger \psi_\uparrow - \psi_\downarrow^\dagger \psi_\downarrow),
\]

where \( \sigma = \uparrow, \downarrow \) are the spin labels. \( c \) has the dimension of \((\text{length})^{-1}\). Because of the attractive interaction, i.e., \( c < 0 \), fermions with opposite spin can form a bound pair with binding energy \( \epsilon_b = \hbar^2 c^2 / 4m \) and spatial extent \( |c|^{-1} \). The parameter \( \gamma = |c|/n \), which is the ratio between the interparticle spacing \((1/n)\) and the width of the bound pair \(|c|^{-1}\), divides the system into a regime of tightly bound pairs (\( \gamma < -1 \)) and overlapping pairs (\(-1 < \gamma < 0\)). For systems with spin polarization, both bound pairs and unpaired fermions coexist. The equilibration between...
attractive Fermi gas are determined by the following dressed energy equations [2,7]:
\[ e^b(\Lambda) = 2 \left( \Lambda^2 - \mu - \frac{c^2}{4} \right) - \int_{-B}^{B} a_2(\Lambda - \Lambda') e^b(\Lambda') d\Lambda' - \int_{-Q}^{Q} a_1(\Lambda - k) e^u(k) dk, \] (2)
\[ e^u(k) = \left( k^2 - \mu - \frac{H}{2} \right) - \int_{-B}^{B} a_1(\Lambda - \Lambda) e^b(\Lambda)d\Lambda, \]
which are obtained from the TBA equations in the limit \( T \to 0 \). In the above equations, \( a_m(\Lambda) = \frac{1}{2\pi} \frac{m}{|e_c^m|^2 + \Lambda^2} \). The dressed energy \( e^b(\Lambda) \leq 0 [e^u(k) \leq 0] \) for \( |\Lambda| \leq B \) (\( |k| \leq Q \)) corresponds to the occupied states. The positive part of \( e^b \) \((e^u)\) corresponds to the unoccupied states. The integration boundaries \( B \) and \( Q \) characterize the Fermi surfaces for bound pairs and unpaired fermions, respectively. The phase boundary can be worked out by analyzing the band fillings with respect to the field \( H \) and the chemical potential \( \mu \) at \( T = 0 \). The (V-F) phase boundary is determined by the conditions \( e^b(0) \leq 0 \) and \( e^b(0) > 0 \), which gives \( \mu_{c3} = -h/2 \). Whereas, the (V-P) phase boundary is determined by the conditions \( e^b(0) > 0 \) and \( e^b(0) \leq 0 \), which gives \( \mu_{c2} = -1/2 \).

The (F-PP) phase boundary is determined by \( e^b(0) \leq 0 \) and \( e^u(\pm Q) = 0 \), which gives the critical field in dimensionless units by
\[ \mu_{c3} = -\frac{1}{2} - \frac{1}{2\pi} [Q - (2\mu_{c3} + h + 1) \arctan Q], \] (3)
with \( Q = \sqrt{2\mu_{c3} + h} \) [18], see the solid (F-PP) phase line \( \mu_{c3} \) in Fig. 1. The most complicated phase boundary indicating the quantum phase transition (P-PP) from a P into a PP phase may be determined by the conditions \( e^b(0) \leq 0 \) and \( e^b(0) = 0 \), i.e., the Fermi sea of unpaired fermion starts filling. Thus, we have
\[ \mu_{c4} = -\frac{h}{2} - \frac{4}{\pi} \int_{-\tilde{B}}^{\tilde{B}} \frac{e^b(\Lambda)d\Lambda}{\Lambda + 4A^2}, \] (4)
\[ e^b(\Lambda) = 2\Lambda^2 - \mu_{c4} - \frac{1}{2} - \frac{1}{\pi} \int_{-\tilde{B}}^{\tilde{B}} \frac{e^b(\Lambda)d\Lambda}{\Lambda + 4A^2}. \]
\[ \tilde{B}^2 = \frac{1}{2} \left( \mu_{c4} + \frac{1}{2} \right) + \frac{1}{2\pi} \int_{-\tilde{B}}^{\tilde{B}} \frac{e^b(\Lambda)d\Lambda}{\Lambda + (\Lambda - \check{\Lambda})^2}, \]
which provide the exact critical field \( \mu_{c4} \), see the solid P-PP line in Fig. 1. In order to study quantum criticality of strong coupling Fermi gases, close forms of critical fields are essential to determine scaling functions of thermodynamical properties. They are
\[ \mu_{c4} = -\frac{h}{2}, \quad \mu_{c2} = -1, \] (5)
\[ \mu_{c3} = -\frac{1}{2} \left( 1 - \frac{2}{3\pi} (h - 1)^{3/2} - \frac{2}{3\pi^2} (h - 1)^2 \right), \] (6)
\[ \mu_{c4} = -\frac{h}{2} + \frac{4}{3\pi} (1 - h)^{3/2} + \frac{3}{2\pi^2} (1 - h)^2. \] (7)
While Eq. (5) applies to all regimes, Eqs. (6) and (7) are expressions in the strongly interacting regime, see the dashed lines in Fig. 1. The above critical fields (6) and (7) can also
be obtained by converting the critical fields in the \( h-n \) plane, which were found in Ref. [7], into the \( \mu-H \) plane.

### III. EQUATION OF STATE

The lack of analytic solutions of the TBA equation has made calculations of physical properties cumbersome and severely limits one's ability to make predictions and to identify the physical origin of observed effects. While bosonization or Luttinger liquid theory can provide qualitative information for low-temperature properties, they do not give equation of states and are accurate only within a limited range of temperatures. The construction of more transparent solutions for thermodynamic functions becomes even more desirable in view of the recent progress in the experiments on 1D Fermi gases with attractive interaction, as well as the successes in deducing an equation of state of Fermi gases from nonuniform density data. A close analytic form of thermodynamic functions will certainly make comparisons between theory and experiments easier.

The thermodynamics of this system has been studied analytically [7,15] and numerically [10,11,13] using TBA equations. Reference [7] studies the free energy at very low temperatures for the spin-balanced case and shows that it is well described by TLL theory. The Luttinger description, however, is incapable of describing quantum criticality for it does not contain the critical fluctuations. TBA equations are a complex set of equations in terms of the so-called dressed energies of bound pairs, unpaired fermions, and spin-wave bound states. In Ref. [15], these equations were recast into coupled equations of thermodynamic quantities, obtained by approximating the dressed energies to the lowest order in \( t \) and taking the \( T|c| \to \infty \) limit for the so-called string contributions, which describe the effect of the spin waves. To describe quantum criticality accurately, however, higher-order terms in \( t \) in the dressed energy have to be retained. (See Ref. [19].) From the TBA equations [2,7], it can be shown that the dressed energies can be calculated in terms of polylogarithmic functions,

\[
e^{b}(k) = 2 \left( \frac{h^2}{2m} k^2 - \mu - \frac{h^2}{2m} \frac{c^2}{4} \right) + \frac{|c|p^b + \mu}{c^2 + k^2} \]

\[
+ \frac{T^{5/2}}{4\sqrt{2\pi} |c|^3} \text{Li}_{5/2}( - e^{\epsilon_b/T}) + \frac{|c|p^b}{\frac{c^2}{4} + k^2} \]

\[
+ \frac{T^{5/2}}{\sqrt{2\pi} |c|^5} \text{Li}_{5/2}( - e^{\epsilon_b/T}) + O \left( \frac{1}{|c|^4} \right),
\]

\( e^{a}(k) = \frac{h^2}{2m} k^2 - \mu - \frac{H}{2} + \frac{p^b}{2} \frac{|c|}{\frac{c^2}{4} + k^2} \]

\[
+ \frac{\sqrt{2}}{\sqrt{\pi}} \frac{1}{|c|^5} \frac{T^{5/2}}{(2\pi)^{3/2}} \text{Li}_{5/2}( - e^{\epsilon_b/T})
\]

\[
- T e^{-H/T} e^{-K} I_0(K) + O \left( \frac{1}{|c|^4} e^{-2H/T} \right),
\]

where

\[
A^b_0 \approx 2\mu + \frac{c^2}{2} - \frac{p^b}{|c|} - \frac{4p^b}{|c|^2},
\]

\[
A^a_0 \approx \mu + \frac{H}{2} - \frac{2p^b}{|c|} - \frac{4p^b}{|c|^2},
\]

\[
\text{Li}_i(z) = \sum_{k=1}^{\infty} \frac{z^k}{k^i},
\]

\( K = \frac{e^{\epsilon_b/T}}{\sqrt{2\pi} |c|^3} \), and \( I_0(x) = \sum_{k=0}^{\infty} \frac{1}{(k!)^2} \) comes from the so-called string or spin-wave contributions. The above result depends on an important observation that the convolution terms in the TBA equations converge quickly as \( e^{\epsilon_b/k} \) and \( e^{\epsilon_b/k} \) become greater than zero at low temperatures. Using the above asymptotic of dressed energies, we can calculate pressure in a straightforward way. Substituting the above-dressed energies into the pressure per unit length \( p = p^b + p^a \),

\[
p^b = \frac{T}{\pi} \int_{-\infty}^{\infty} dk \ln(1 + e^{-\epsilon_b/k}/T),
\]

\[
p^a = \frac{T}{2\pi} \int_{-\infty}^{\infty} dk \ln(1 + e^{-\epsilon_a/k}/T),
\]

and taking integration by part, thus, we obtain the following dimensionless form of the pressure of the system as

\[
\tilde{p}(t, \tilde{\mu}, \tilde{h}) \equiv \frac{p}{(|c|e^{\epsilon_b})} = \tilde{p}^b + \tilde{p}^a,
\]

where \( \tilde{p}^b \) and \( \tilde{p}^a \) can be interpreted as the pressure of the bound pair and unpaired fermions and are coupled through the following set of equations:

\[
\tilde{p}^b = -\frac{t^{3/2}}{2\sqrt{\pi}} \text{F}^b_{3/2} \left[ 1 + \frac{\tilde{p}^b}{8} + 2\tilde{p}^a \right] + O(t^4),
\]

\[
\tilde{p}^a = -\frac{t^{3/2}}{2\sqrt{\pi}} \text{F}^a_{3/2} \left[ 1 + \frac{\tilde{p}^a}{8} \right] + O(t^4),
\]

\[
\frac{X_b}{t} = \frac{v_b}{t} - \frac{\tilde{p}^b}{t} - \frac{4p^b}{t} - \frac{t^{3/2}}{2\sqrt{\pi}} \left( \frac{1}{16} f^b_{5/2} + \sqrt{2} f^a_{5/2} \right),
\]

\[
\frac{X_a}{t} = \frac{v_a}{t} - \frac{\tilde{p}^a}{t} - \frac{t^{3/2}}{2\sqrt{\pi}} f^a_{5/2} + e^{-h^2/t} e^{-K} I_0(K),
\]

where the functions \( F^b_{n}, F^a_{n}, f^b_{n}, \) and \( f^a_{n} \) are defined as

\[
F^b_{n} \equiv \text{Li}_n(-e^{\epsilon_b/T}), \quad F^a_{n} \equiv \text{Li}_n(-e^{\epsilon_a/T}),
\]

\[
f^b_{n} \equiv \text{Li}_n(-e^{\epsilon_b/T}), \quad f^a_{n} \equiv \text{Li}_n(-e^{\epsilon_a/T}),
\]

where \( v_b = 2\tilde{\mu} + 1, v_a = \tilde{\mu} + h/2, \) and \( X_b, X_a \) are defined as in Eqs. (14) and (15).

The derivation of Eqs. (12)–(15) is very involved. The reason why we present these equations is to prepare for later discussions of the mathematical manipulation needed to extract the singularity near the quantum critical point. To solve these equations, one substitutes Eqs. (14) and (15) into Eqs. (12) and (13). This gives two coupled equations of \( \tilde{p}^b \) and \( \tilde{p}^a \), which can be solved by iteration. From Eqs. (14) and (15), we can rewrite the functions \( \text{Li}_{3/2}(-e^{\epsilon_b/T}) \) and \( \text{Li}_{5/2}(-e^{\epsilon_a/T}) \) in terms of the functions \( f^b_{n} \) and \( f^a_{n} \). After lengthy algebra, the pressures are given by \( \tilde{p} = \sqrt{2} \tilde{p}^b + \tilde{p}^a \) with

\[
\tilde{p}^s = -\frac{t^{3/2}}{2\sqrt{\pi}} \left[ f^b_{3/2} + t^{1/2} Y^s_{1/2} + t Y^s_1 + \frac{3}{2} Y^s_{3/2} + O(t^2) \right],
\]

where \( x = b, u \) and \( (Y^u_{n}) \) and \( (Y^u_{n}) \) are given by

\[
Y^u_{1/2} = \frac{1}{\sqrt{\pi}} f^u_{1/2} \left( \frac{1}{2} f^a_{3/2} + \sqrt{2} f^a_{5/2} \right),
\]

\[
Y^u_{1/2} = \frac{1}{\sqrt{\pi}} f^u_{1/2} f^b_{1/2}.
\]
The expressions of $Y^b_1$ and $Y^u_2$ are given in the Appendix. The accuracy of Eq. (17) is shown in Fig. 2, where the result of the expansion is compared with the numerical solution of the recast TBA equations. Equations (12)–(15) served as the equation of state (represented by circles). The vertical dotted line represents the Fermi temperature of the recast TBA equations. Equations (12)–(15) serve as a driving parameter $\tilde{\mu}_b$ and $\tilde{\mu}_u$ for fixed total density $\tilde{\rho}$, the effective chemical potentials for pairs and unpaired fermions are given by

$$
\tilde{\mu}_b \approx \frac{\hbar^2 n^2 \pi^2}{2m} (1 - p)^2,
$$

$$
\tilde{\mu}_u \approx \frac{\hbar^2 n^2 \pi^2}{2m} p^2,
$$

where $p = (n_{1} - N_{1})/(n_{1} + N_{1})$ is the polarization. This result reflects the fact that the system reduces to a mixture of hard-core boson (mass $2m$) and a gas of unpaired fermions (mass $m$) in this limit. Since hard-core bosons in 1D behave like fermions, the thermodynamics of the system is that of a mixture of two Fermi gases with masses $2m$ and $m$.

**IV. QUANTUM CRITICALITY**

Quantum critical behaviors are reflected in the singularities in thermodynamic quantities, such as density $\tilde{\rho} = n/|c|$, compressibility $\tilde{\kappa} = \partial \tilde{\rho} / \partial \tilde{\mu}$, and magnetization $\tilde{M} = M/|c|$, which are derivatives of pressure $p$ with respect to $\mu$ and $h$. Such singularities, however, cannot be obtained by directly differentiating the expansion, Eq. (17). The reason is that, even though Eq. (17) gives a highly accurate value for the pressure with a few terms, all higher-order terms that contribute insignificantly to the pressure have singularities when differentiated with respect to $\mu$. To account for these singular structures, say, in the density, one must first differentiate Eqs. (12)–(15) with respect to $\tilde{\mu}$ and $\tilde{\kappa}$ and then solve for these quantities by iteration. Quantum phase transition occurs as the driving parameters $\tilde{\mu}$ and $\tilde{\kappa}$ cross the phase boundaries at zero temperature. At very low temperatures, $T \ll \epsilon_b$ (Boltzmann’s constant $k_B = 1$), the thermodynamics of the 1D FFLO-like phase is governed by the linearly dispersing phonon modes, i.e., the long-wavelength density fluctuations of the two weakly coupled gases. In this low-temperature regime, spin strings are suppressed. The suppression of spin fluctuations leads to a universality class of a two-component TLL in the gapless phase of FFLO, where the charge-bound states form hard-core composite bosons. The leading low-temperature corrections to the free energy give [7,15]

$$
f \approx f_0 - \frac{\pi T^2}{6\hbar} \left( \frac{1}{v_b} + \frac{1}{v_u} \right). \quad (24)
$$

bound pairs interfere with each other and with excess fermions. The $Y$ terms in Eq. (17) can be viewed as interactions of boson-boson and boson-fermion clusters of increasing size. We find that the pressure, Eq. (17), can reach 95% accuracy for $T/\epsilon_b = 0.2$ by including up to the $Y^4$ terms and has less than 1% error if one includes the $Y^5/2$ terms, see Fig. 2.

Finally, we note that, in the limit $|c| \to \infty$, the pressure

$$
P(x) \approx \frac{2\sqrt{2}}{3\pi} \left( \frac{m}{\hbar^2} \right)^{3/2} \left[ 1 + \frac{\pi^2}{8} \left( \frac{T}{\epsilon_b} \right)^2 + \frac{7\pi^4}{640} \left( \frac{T}{\epsilon_b} \right)^4 \right]
$$

is the pressure of a 1D Fermi gas with mass $m$. In this limit, for fixed total density $n$, the effective chemical potentials for pairs and unpaired fermions are given by

$$
\tilde{\mu}_b \approx \frac{\hbar^2 n^2 \pi^2}{2m} (1 - p)^2,
$$

$$
\tilde{\mu}_u \approx \frac{\hbar^2 n^2 \pi^2}{2m} p^2,
$$

up to the order of $Y^{(a,b)}_1$, we can rewrite the pressure (17) as

$$
P^b \approx \tilde{P}^b - \tilde{n}^b \tilde{\epsilon}^b + 4\tilde{\rho}^b + 8\tilde{n}^u \tilde{\rho}^b + 4\tilde{n}^u \tilde{\epsilon}^b
$$

$$
+ \tilde{\kappa}_o \left( 8\tilde{P}^b \tilde{\rho}^b + \frac{1}{2} \tilde{P}^u \tilde{\epsilon}^b + 4\tilde{\rho}^u \tilde{\rho}^b + 2\tilde{\rho}^u \tilde{\rho}^b \right),
$$

which gives an insight into understanding the cluster-cluster effect. From these analytical expressions of pressure, we see that the
Here, \( f_0 \) is the ground-state energy, and \( v_{b,u} \) are the sound velocities of pairs and unpaired fermions, i.e.,
\[
    v_b \approx \frac{v_F(1 - P)}{4} \left( 1 + \frac{(1 - P)}{\vert \gamma \vert} + 4P \right)
\]
\[
    v_u \approx \frac{v_F P}{4} \left( 1 + \frac{4(1 - P)}{\vert \gamma \vert} \right)
\]
(25)

Here, the Fermi velocity is \( v_F = \hbar \pi n/m \). The TLL is maintained below the crossover temperature at which the relation of the linear temperature-dependent entropy (or specific) heat breaks down. The equations of state, Eqs. (12)–(15), and the TLL nature (24) allow one to quantitatively investigate quantum criticality of the Fermi gas, see Fig. 3.

Using the standard thermodynamic relations, we can derive close forms of density, magnetization, and compressibility, which allow one to capture universal low-temperature thermodynamics of the Fermi gas as well as critical phenomena. Without losing generality, we can safely ignore spin-wave contribution at quantum criticality due to its exponentially small contribution as \( T \to 0 \). For our convenience in calculating the thermodynamical properties, we denote
\[
    f_n^{A_b} \equiv L_n(-e^{A_b/\gamma}), \quad A_b \equiv \frac{v_b}{t} + \frac{1}{2} \left( \frac{f_b^{1/2}}{\sqrt{\pi}} + \sqrt{\pi} f_b^{3/2} \right)
\]
\[
    f_n^{A_u} \equiv L_n(-e^{A_u/\gamma}), \quad A_u \equiv \frac{v_u}{t} + \frac{1}{2} \left( \frac{f_u^{1/2}}{\sqrt{\pi}} + \sqrt{\pi} f_u^{3/2} \right)
\]
(26)

From Eqs. (12)–(15), we derived the total density \( \bar{n} \),
\[
    \bar{n} = -\frac{\sqrt{\bar{r}}}{\sqrt{\pi} \Delta} \left\{ \frac{1}{2 \sqrt{2}} f_{1/2}^{A_b} \left[ 1 + \frac{3\sqrt{\bar{r}}}{2 \sqrt{\pi}} f_{1/2}^{A_b} - \frac{47\sqrt{\bar{r}}}{16 \sqrt{\pi} f_{1/2}^{A_b}} \right] + f_{1/2}^{A_u} \right\}
\]
(27)

with
\[
    \Delta = 1 - \frac{\sqrt{\bar{r}}}{2 \sqrt{\pi}} f_{1/2}^{A_b} - \frac{t}{\sqrt{\pi}} f_{1/2}^{A_u} - \frac{t^2}{16 \sqrt{\pi} f_{1/2}^{A_b}}
\]
(28)

The density in dimensionless scale naturally services as the dimensionless equation of state, which contains two free-fermion-like densities with a singular behavior near different critical points. The interaction binding energy rescales temperature. This close form of the equation of state is very convenient for performing the fitting of experimental finite-temperature density profiles of the 1D trapped gas within local-density approximation, see Refs. [13,20].

Similarly, magnetization \( \bar{M} = (\bar{n}_u - \bar{n}_d)/2 \),
\[
    \bar{M} = -\frac{\sqrt{\bar{r}}}{2 \sqrt{\pi} \Delta} \left\{ \frac{1}{2 \sqrt{2}} f_{1/2}^{A_b} \left[ 1 - \frac{3\sqrt{\bar{r}}}{2 \sqrt{\pi}} f_{1/2}^{A_b} - \frac{31\sqrt{\bar{r}}}{16 \sqrt{\pi} f_{1/2}^{A_b}} \right] + f_{1/2}^{A_u} \right\}
\]
and compressibility \( \bar{k} = \chi \epsilon_b/\bar{c} \) with \( \chi = \partial M/\partial H \),
\[
    \bar{k} = -\frac{1}{\sqrt{\pi} \Delta^3} \left\{ \frac{1}{\sqrt{\bar{r}}} f_{-1/2}^{A_b} \left[ 1 + \frac{3\sqrt{\bar{r}}}{2 \sqrt{\pi}} f_{1/2}^{A_b} + \frac{2\sqrt{\bar{r}}}{\pi} f_{1/2}^{A_u} f_{1/2}^{A_b} \right] + \frac{2\sqrt{\bar{r}}}{\sqrt{\pi}} f_{1/2}^{A_u} \right\}
\]
(29)

and susceptibility \( \bar{\chi} = \chi \epsilon_b/\bar{c} \) with \( \kappa = \partial n/\partial \mu \),
\[
    \bar{\chi} = -\frac{1}{\sqrt{\pi} \Delta^3} \left\{ \frac{1}{\sqrt{\bar{r}}} f_{-1/2}^{A_b} \left[ 1 - \frac{5\sqrt{\bar{r}}}{2 \sqrt{\pi}} f_{1/2}^{A_b} - \frac{t}{4 \pi} \left( f_{1/2}^{A_b} \right)^2 \right] + \frac{2\sqrt{\bar{r}}}{\sqrt{\pi}} f_{1/2}^{A_u} \right\}
\]
(30)

The Fermi liquid of excess fermions (excess fermions) become a regular part of the background, meanwhile, the ones of the Fermi liquid of excess fermions can be derived in a systematic way.

Quantum criticality describes strongly coupled thermal and quantum fluctuations of matter as quantum phase transitions take place at zero temperature. Such quantum phase transitions are uniquely characterized by the critical exponents depending only on the dimensionality and the symmetry of the system. Here, we show that scaling functions at quantum criticality can be calculated from the above close forms of thermodynamical properties. Near the critical points, we expand thermodynamical properties in the limit \( |\mu - \mu_c| \ll 1 \). For the quantum critical regime, i.e., \( T > |\mu - \mu_c| \), we find that the thermodynamical properties of the Fermi liquid of bound pairs (excess fermions) become a regular part of the background.
(bound pairs) become a singular part. Near the $T = 0$ phase boundaries, we find that $\tilde{n}$ and $\tilde{M}$ have universal scaling forms

\begin{align}
\text{(V-F): } \tilde{n} &\approx -\frac{\sqrt{t}}{2\sqrt{2\pi}} \text{Li}_{1/2} \left\{ -\exp \left( \frac{(\tilde{\mu} - \mu_c)}{t} \right) \right\}, \\
\text{(F-PP): } \tilde{M} &\approx -\frac{\sqrt{t}}{4\sqrt{2\pi}} \text{Li}_{1/2} \left\{ -\exp \left( \frac{(\tilde{\mu} - \mu_c)}{t} \right) \right\}, \\
\text{(F-P): } \tilde{n} &\approx n_{a3} - \lambda_1 \sqrt{t} \text{Li}_{1/2} \left\{ -\exp \left( \frac{2(\tilde{\mu} - \mu_c)}{t} \right) \right\}, \\
\text{(V-P): } \tilde{M} &\approx M_o + \lambda_3 \sqrt{t} \text{Li}_{1/2} \left\{ -\exp \left( \frac{2(\tilde{\mu} - \mu_c)}{t} \right) \right\}, \\
\end{align}

where $n_{a3}$ and $n_{a4}$ are the background densities near the critical points $\mu_3$ and $\mu_4$, respectively. At quantum criticality, the above densities can be cast into a universal scaling form, e.g., Refs. [14,21–23],

\begin{align}
n_o(\mu, T) &= n_0 + T^{(d/2)+1-1/(z\nu)} g \left( \frac{\mu - \mu_c}{T^{1/z}} \right), 
\end{align}

where the dynamic exponent $z = 2$ and the correlation exponent $\nu = 1/2$ can be read off the scaling functions within the expressions (31)–(38) from which the physical origin of quantum criticality is conceivable.

![Fig. 4](https://example.com/fig4.png)
the left panel shows $\tilde{n}$ vs $\tilde{\mu}$ across the V-F phase boundary, Eq. (31). The right panel shows $\tilde{n} - \tilde{n}_F$ vs $\tilde{\mu}$ across the F-PP phase boundary, Eq. (33). The intersections of these curves yield the critical value $\mu_c$ at $T = 0$. In these figures, we displayed temperature variations from $t = 0.01$ to $t = 0.04$. The former corresponds to $T/T_F = 0.1$ in the recent Rice setup, which is the temperature in the current Rice experiment [13].

In general, the slope of densities at the quantum criticality can be written as the following universal scaling form near the critical points:

$$\langle n(t, \tilde{\mu}) - n_0 \rangle r^{-1/2} = \lambda \sum_{m=0}^{\infty} c_m x^m,$$

where $x = \frac{\tilde{\mu} - \mu_c}{t}$ and the coefficients $c_m = \frac{1}{m!} \text{Li}_{1/2-m}(-1)$. The intersection behavior can accurately determine the temperature from the slopes near the intersection point. For a given polarization (or say fixed polarization), $\lambda$ becomes constant [see Eqs. (31)–(38)]. Thus, the slopes are fixed by temperatures. Perhaps this scaling behavior is a good thermometry [24].

Finally, we would like to mention that similar plots can be constructed for compressibility across all phase boundaries, see Fig. 7. For compressibility, it is important (as stressed before) to include all higher-order terms in Eq. (17), as they are all singular at criticality; and such inclusion can be achieved efficiently by taking derivatives of Eq. (27) with respect to $\tilde{\mu}$ together with performing a proper iteration via Eqs. (12)–(15).

The expression of the critical behavior near various phase boundaries is given by

**V-F:** $\tilde{k} \approx -\frac{1}{2\sqrt{2\pi t}} \text{Li}_{1/2} \left\{-\exp \left[\frac{(\tilde{\mu} - \mu_{c1})}{t}\right] \right\}$, (42)

**F-PP:** $\tilde{k} \approx \kappa_{03} - \frac{\lambda_4}{\sqrt{t}} \text{Li}_{1/2} \left\{-\exp \left[\frac{(\tilde{\mu} - \mu_{c2})}{t}\right] \right\}$, (43)

**V-P:** $\tilde{k} = -\frac{2}{\sqrt{\pi t}} \text{Li}_{1/2} \left\{-\exp \left[\frac{(\tilde{\mu} - \mu_{c3})}{t}\right] \right\}$, (44)

**P-PP:** $\tilde{k} = \kappa_{04} - \frac{\lambda_5}{\sqrt{t}} \text{Li}_{1/2} \left\{-\exp \left[\frac{(\tilde{\mu} - \mu_{c4})}{t}\right] \right\}$, (45)

where $\kappa_{03}$, $\kappa_{04}$, $\lambda_4$, and $\lambda_5$ are given by

$$\kappa_{03} = \frac{1}{2\pi \sqrt{t}}, \quad \lambda_4 = \frac{2}{\sqrt{\sqrt{2} \pi}} \left(1 + \frac{\sqrt{\alpha}}{2\pi^2} \right),$$

$$\kappa_{04} = \frac{2}{\pi \sqrt{b}} \left(1 + \frac{3\sqrt{b}}{\sqrt{x}} \right),$$

$$\lambda_5 = \frac{1}{2\pi \sqrt{2}} \left(1 + \frac{2\sqrt{b}}{\pi^2} - \frac{10b}{x} \right).$$

The critical exponents $z = 2$ and $\nu = 1/2$ can be read off the universal scaling function,

$$\kappa(\mu, T) = \kappa_0 + T^{(4/5)+1-(2/5z)} F \left(\frac{\mu - \mu_c}{T^{1/4} \nu c} \right),$$

with a universal scaling function $F(x) = \text{Li}_{1/2}(x)$. 

**FIG. 5.** (Color online) Magnetization $M$ and density $\rho$ vs chemical potential $\mu$ at different temperatures. The intersections in the right and left panels give the phase boundaries of the V-P and P-PP transitions, respectively.

**FIG. 6.** (Color online) Density vs chemical potential: The right panel shows the intersection of the density difference $(\tilde{n} - \tilde{n}_F)\sqrt{T}$ at different temperatures, which gives the F-PP phase boundary. Here, we have $\tilde{n}_F = -\frac{\sqrt{T}}{2\pi} \text{Li}_{1/2}(-e^{4t/\sqrt{T}})$ with $A_{\tilde{\mu}} \approx v_F + \sqrt{T} f_{\tilde{\mu}} / \sqrt{\pi}$. It becomes the density of a free-fermion system in the vicinity of the F-PP phase boundary, i.e., $A_{\tilde{\mu}}$ reduces to $v_F$. The left panel shows the intersection of densities that gives the V-F phase boundary. It also shows that the scaling form begins to fail for $t \geq 0.03$.

**FIG. 7.** (Color online) Compressibility $\sqrt{T}$ (dimensionless) vs $\mu$ for $h = 1.1$ at different values of $t$. At the critical point $\mu_{c3}$, there is a background compressibility. The curves truly intersect at a single point after the background is removed.
VI. CONCLUSION

We have studied the quantum critical phenomena of strongly attractive 1D Fermi gases via an exact BA solution. We have obtained the equation of state with high precision from zero temperature up to the temperature scale of binding energy. From the equation of state, we have obtained the exact scaling form for density, compressibility, and spin susceptibility in the vicinity of the $T = 0$ phase boundaries between different phases. These scaling forms illustrate the universal TLL signature and the physical origin of quantum criticality. The excitations near various phase boundaries are such that their critical behaviors are either described by that of free fermions or that of mixtures of fermions with masses $m$ and $2m$.

Our exact results can help analyze the recent experiments on attractive 1D spin-imbalanced atomic Fermi gas [13]. It can also help to verify the working of an algorithm for determining the susceptibility in the vicinity of the exact scaling form for density, compressibility, and spin from zero temperature up to the temperature scale of binding strongly attractive 1D Fermi gases via an exact BA solution.

APPENDIX: COEFFICIENTS

The pressures (12) and (13) provide the precise equation of states for studying two-component Fermi gases with population imbalance. By iteration, we found the analytical equation of state (17), which provides a deep insight into the many-body effect in the so-called FFLO phase. The first two coefficients are given in Eq. (18). The higher-order correction terms are given by

$$Y_{3/2}^b = \frac{1}{\pi^{3/2}} \left\{ f_{1/2}^b \left[ \frac{\sqrt{2}}{8} (f_{3/2}^b)^2 f_{3/2}^u + \frac{1}{2} (f_{3/2}^u)^2 f_{1/2}^b + \frac{3}{4} (f_{3/2}^b)^3 + \frac{\sqrt{2}}{3} (f_{3/2}^u)^3 \right] + f_{1/2}^b \left[ \frac{3}{16} (f_{3/2}^b)^2 f_{1/2}^2 + \frac{1}{2} (f_{3/2}^u)^2 f_{1/2}^b + \frac{3}{2} (f_{3/2}^b)^2 f_{1/2}^b + 2 f_{3/2}^b f_{5/2}^u f_{1/2}^b + \frac{3 \sqrt{2}}{4} f_{3/2}^u f_{3/2}^b \right] + f_{1/2}^b \left[ \frac{1}{\sqrt{2}} (f_{3/2}^b)^2 f_{3/2}^u + \frac{1}{8} (f_{3/2}^u)^2 f_{3/2}^b + \frac{1}{\sqrt{2}} (f_{3/2}^b)^2 f_{3/2}^u + 2 f_{3/2}^b f_{3/2}^u f_{3/2}^b + \frac{2}{\sqrt{2}} f_{1/2}^b f_{3/2}^u f_{3/2}^b \right] \right\}$$

$$- \frac{1}{\pi^{3/2}} \left\{ \frac{1}{6} (f_{3/2}^b)^3 f_{3/2}^u + f_{1/2}^b \left[ \frac{1}{8} (f_{3/2}^b)^2 f_{3/2}^u + (f_{3/2}^b)^2 f_{1/2}^b + \frac{1}{\sqrt{2}} f_{3/2}^u f_{3/2}^b f_{3/2}^b \right] + f_{1/2}^b \left[ \frac{1}{2} (f_{3/2}^b)^2 f_{1/2}^b + \frac{1}{\sqrt{2}} (f_{1/2}^b)^2 f_{3/2}^b + \frac{1}{4} (f_{3/2}^b)^2 f_{3/2}^b f_{1/2}^b + \frac{2}{\sqrt{2}} f_{3/2}^u f_{3/2}^b f_{3/2}^b \right] \right\}$$

which reveal the cluster-cluster interacting effect.

[18] Our approach is different from that of Ref. [5]. Equation (8) in Ref. [5] can be expressed as
\[ \mu = -\frac{1}{2} - \frac{1}{2\pi} (2Q - (2\mu + 2h + 1)\tan^{-1}2Q) \]
with \( Q = \sqrt{\frac{(\mu + h)}{2}} \) in dimensionless units, which is the same as our result (3) via a rescaling \( h \rightarrow h/2 \).
[19] The equations in Ref. [15] are obtained by (i) approximating the \([\cdots]\) in Eqs. (12) and (13) by 1, (ii) omitting the \( t^{3/2} \) correction terms in Eq. (15), and (iii) taking the \( T_c \rightarrow \infty \) in the string equations (2).

[20] The figure was prepared by X.-G. Yin. The analytical result of quantum criticality obtained in this paper (e-print arXiv:1010.130) has inspired further study of quantum critical phenomena of the Fermi gases in a harmonic trap, see X.-G. Yin, X.-W. Guan, S. Chen, and M. T. Bachelor, Phys. Rev. A 84, 011602(R) (2011).
